The title compound, $\mathrm{C}_{14} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{O}_{4}$, was obtained from 2-acetyl-6-aminonaphthalene through two-step reactions of acetylation and nitration. The molecule comprises the naphthalene ring system consisting of functional systems bearing a acetyl group (C-2), a nitro group (C-5), and an acetylamino group (C-6). In the crystal, the molecules are assembled into two-dimensional sheetlike structures by intermolecular $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen-bonding interactions. Hirshfeld surface analysis illustrates that the most important contributions to the crystal packing are from $\mathrm{O} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{O}(43.7 \%), \mathrm{H} \cdots \mathrm{H}$ ( $31.0 \%$ ), and $\mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}(8.5 \%)$ contacts.

## 1. Chemical context

Organic small molecules with naphthalene ring systems are attractive photonic materials due to their high photoluminescence quantum efficiency, color tunability, and sizedependent optical properties (Wang et al., 2012; Yao et al., 2013). Modifying the organic molecular structure can tune the intermolecular hydrogen-bonding and $\pi-\pi$ stacking interactions, which influence their packing mode during selfassembly and determine the final aggregated structures. The molecular stacking patterns in crystals can affect asymmetric light propagation (Yagai et al., 2012; Zou et al., 2018; Zhang et al., 2018).

The title compound (I), $N$-(6-acetyl-1-nitronaphthalen-2yl)acetamide, obtained from 2-acetyl-6-aminonaphthalene through two-step reactions of acetylation and nitration, is a Prodane fluorescent dye with red fluorescence and a large Stoke shift (Xu et al., 2017). The stacking of naphthalene compounds into crystals depends on intermolecular hydrogen bonds and $\pi-\pi$ stacking interactions. The nitro group and the acetylamino group of the naphthalene ring system will affect intermolecular interactions, making it possible to change the one- or two-dimensional stacking arrangement, which in turn

Figure 1
The molecular structure of the title compound (I) with the atomic numbering scheme. Displacement ellipsoids are depicted at the $50 \%$ probability level.
affects photo-ion conduction (Eya'ane Meva et al., 2012; Nguyen et al., 2004).

## 2. Structural commentary

The molecular structure of the title compound (I) is shown in Fig. 1. The molecules are semi-rigid and almost fully coplanar, except for the nitro oxygen atoms and methyl hydrogen atoms. Notably, compound (I) has a primary amine group on the naphthalene core, while the reactant has a secondary amine at the same position. It may have more steric repulsion with neighboring molecules compared to the reactant when assembled into 2D structures. Self-assembly of naphthalene framework organic molecules through $\pi-\pi$ stacking forms 3D sheet-like structures with uniform dimensions.

In compound (I), the nitro group and acetylamino group are adjacent, located at positions C-5 and C-6, respectively, and

Figure 2
The packing of molecules in the title compound (I), viewed along the $b$ axis direction ( $\mathrm{N} 2-\mathrm{H} 2 \cdots \mathrm{O} 1$ hydrogen bonds are shown as orange dashed lines, $\mathrm{C} 7-\mathrm{H} 7 \cdots \mathrm{O} 2$ and $\mathrm{C} 4-\mathrm{H} 4 \cdots \mathrm{O} 2$ hydrogen bonds are shown as gray dashed lines).

Table 1

Symmetry codes: (i) $x, y, z+1$; (ii) $x+1, y, z$.
the acetyl group is located at the 2-position of the naphthalene ring system. The angle between the two oxygen atoms on the nitro group located at positions C-5 is $123.93(18)^{\circ}$, and the torsion angles $\mathrm{C} 6-\mathrm{C} 5-\mathrm{N} 1-\mathrm{O} 3$ and $\mathrm{C} 10-\mathrm{C} 5-\mathrm{N} 1-\mathrm{O} 3$ are $-90.34(15)$ and $89.66(15)^{\circ}$, respectively. The angles of the acetyl group at the 2-position, $\mathrm{O} 1-\mathrm{C} 11-\mathrm{C} 2$ and $\mathrm{O} 1-\mathrm{C} 11-\mathrm{C} 12$, are $120.13(18)$ and $120.52(18)^{\circ}$, respectively. In addition, the dihedral angle between the nitro group and the plane through the naphthalene ring system is $89.66(15)^{\circ}$.

## 3. Supramolecular features

In the crystal, a unit cell contains four molecules, which exhibit a centrosymmetric arrangement (Fig. 2), and hydrogen bonding and $\pi-\pi$ stacking interactions were responsible for the formation of the crystal structures with distinct morphologies.

The growth pattern for the title compound (I) is a 1D wirelike structure and hydrogen bonding advances the growth along the $a$-axis direction. The molecules are linked via $\mathrm{N} 2-\mathrm{H} 2 \cdots \mathrm{O} 1$ hydrogen bonds, generating 2D layers propagating along the [010] axis direction (Table 1). Without hydrogen-bonding and other strong interactions between molecules in adjacent layers, $\pi-\pi$ stacking interactions, with centroid-centroid distcances of $3.67 \AA$, are the predominant driving force during self-assembly, which facilitates the crystal of the title compound growth along the [010] direction, forming a 3D structure (Meva et al., 2012; Nguyen et al., 2004). Weak $\mathrm{C} 4-\mathrm{H} 4 \cdots \mathrm{O} 2$ contacts are also observed.

## 4. Hirshfeld Surface analysis

A Hirshfeld surface analysis was performed and the associated fingerprint plots, which provide a 2 D view of the intermolecular interactions within molecular crystals, were gener-

Figure 3
Front view of the three-dimensional Hirshfeld surface of the title compound (I) mapped over $d_{\text {norm }}$.

Figure 4
Hirshfeld surface mapped over $d_{\text {norm }}$ for the title compound (I) showing: $\mathrm{H} \cdots \mathrm{O} / \mathrm{O} \cdots \mathrm{H}$ (upside and downside) contacts.
ated using Crystal Explorer 21.5 (Spackman et al., 2021), with a standard resolution of the 3D $d_{\text {norm }}$ surfaces plotted over a fixed color scale of -0.1253 (red) to 1.4046 (blue) arbitrary units (Fig. 3). The N2-H2 . OO1 hydrogen bond was identified to be a crucial structure-forming interaction within the crystal packing. The intense red spots symbolizing short contacts and negative $d_{\text {norm }}$ values on the surface are related to the presence of the $\mathrm{N} 2-\mathrm{H} 2 \cdots \mathrm{O} 1$ hydrogen bonds in the crystal structure. The weak $\mathrm{C} 4-\mathrm{H} 4 \cdots \mathrm{O} 2$ contacts are indicated by faint red spots (Fig. 4).

The 2D fingerprint plots for the $\mathrm{H} \cdots \mathrm{O} / \mathrm{O} \cdots \mathrm{H}, \mathrm{H} \cdots \mathrm{H}$, $\mathrm{H} \cdots \mathrm{C} / \mathrm{C} \cdots \mathrm{H}$, and $\mathrm{H} \cdots \mathrm{N} / \mathrm{N} \cdots \mathrm{H}$ contacts are shown in Fig. 5. The most significant interactions are $\mathrm{H} \cdots \mathrm{O} / \mathrm{O} \cdots \mathrm{H}$, which play a defining role in the overall crystal packing, contributing $43.7 \%$, and are located in the tip and middle region of the fingerprint plot. $\mathrm{H} \cdots \mathrm{H}$ interactions contribute $31.0 \%$, being located in the middle region of the fingerprint plot. The contributions of the weak $\mathrm{H} \cdots \mathrm{C} / \mathrm{C} \cdots \mathrm{H}$ and $\mathrm{H} \cdots \mathrm{N} / \mathrm{N} \cdots \mathrm{H}$ contacts to the Hirshfeld surface are 8.5 and $1.1 \%$, respectively.

Shape-index and curvedness are the metrics that describe the local shape in terms of principal curvatures, representing the surface properties of the crystal molecule to determine their arrangements. The Hirshfeld surface mapped over electrostatic potential, shape-index, curvedness and fragment patches is shown in Fig. 6. The electrostatic potential map (Fig. $6 a$ ) highlights the electronegative (red) and electropositive (blue) regions in the molecule. The molecule shows red colored regions near the oxygen atom (O1), indicating the electronegative spots (Akhileshwari et al., 2021). The pattern of red and blue triangles on the shape-index map (Fig. 6b)

Figure 5
The two-dimensional fingerprint plots of the title compound (I), showing (a) all interactions, and delineated into (b) $\mathrm{H} \cdots \mathrm{H},(c) \mathrm{O} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{O},(d)$ $\mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}$, and $(e) \mathrm{N} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{N}$ interactions [The $d_{\mathrm{e}}$ and $d_{\mathrm{i}}$ values represent the distances (in $\AA$ ) from a point on the Hirshfeld surface to the nearest atoms inside and outside the surface, respectively.]
shows feature characteristic of $\pi-\pi$ interactions. As the molecule shows flat regions on the curvedness map (Fig. 6c), it is evident that the title molecule is arranged in planar stacking (Spackman \& Jayatilaka, 2009). The fragment patches (Fig. $6 d$ ) illustrates the coordination number of the corresponding atoms in the compound.

## 5. Synthesis and crystallization

1.0 g of 2-acetyl-6-aminonaphthalene were dissolved in 35 ml of $\mathrm{Ac}_{2} \mathrm{O}$, stirred for 10 minutes, and 30 ml of $\mathrm{CH}_{3} \mathrm{COOH}$ were added, followed by the slow addition of 6.5 ml of concentrated $\mathrm{HNO}_{3}$ under ice-bath conditions for 3 h at room temperature. When the reaction was complete, it is extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$

Figure 6
Hirshfeld surface of the title compound (I) mapped over (a) electrostatic potential, (b) shape-index, (c) curvedness, and (d) fragment patches.
three times, the organic phase was combined, the positive silica gel column was passed under normal pressure after spinning (eluent $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ :ethyl acetate, 10:1). The eluent containing the product components was collected and the light-yellow solid was concentrated. It was dissolved in methanol and placed in a refrigerator at 277 to cultivate lightyellow transparent square crystals (Xu et al., 2017). The MeOH was dissolved and red transparent square crystals suitable for X-ray diffraction were were obtained at 277 K in the refrigerator.

## 6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. H atoms were positioned geometrically $(\mathrm{C}-\mathrm{H}=0.93-0.95 \AA)$ and allowed to ride on their parent atoms, with $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$ or $1.5 U_{\text {eq }}$ (C-methyl).

## Acknowledgements

The authors thank Hubei Normal University and Nian Zhao for recording the X-ray crystallographic data for the crystals.

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
