A new $\mathrm{Gd}^{3+}$ coordination polymer (CP), namely, poly[diaqua[ $\mu_{4}-1^{\prime}$-carboxy-3,3'-(diazene-1,2-diyl)dibenzene-1,2,2'-tricarboxylato]gadolinium(III)], [Gd$\left.\left(\mathrm{C}_{16} \mathrm{H}_{7} \mathrm{~N}_{2} \mathrm{O}_{8}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]_{n}$, (I), has been synthesized hydrothermally from $\mathrm{Gd}\left(\mathrm{NO}_{3}\right)_{3}$. $6 \mathrm{H}_{2} \mathrm{O}$ and azobenzene-2, $2^{\prime}, 3,3^{\prime}$-tetracarboxylic acid ( $\mathrm{H}_{4} \mathrm{abtc}$ ). The target solid has been characterized by single-crystal and powder X-ray diffraction, elemental analysis, IR spectroscopy and susceptibility measurements. CP (I) crystallizes in the monoclinic space group $C 2 / c$. The structure features a 4 -connected topology in which $\mathrm{Gd}^{3+}$ ions are connected by carboxylate groups into a linear chain along the monoclinic symmetry direction. Adjacent one-dimensional aggregates are bridged by Habtc ${ }^{3-}$ ligands to form a two-dimensional CP in the (10 $\overline{1}$ ) plane. A very short hydrogen bond $[\mathrm{O} \cdots \mathrm{O}=2.4393$ (4) $\AA$ ] links neighbouring layers into a three-dimensional network. A magnetic study revealed antiferromagnetic Gd..Gd coupling within the chain direction. CP (I) displays a significant magnetocaloric effect (MCE), with a maximum $-\Delta S_{\mathrm{m}}$ of $27.26 \mathrm{~J} \mathrm{~kg}^{-1} \mathrm{~K}^{-1}$ for $\Delta H=7 \mathrm{~T}$ at 3.0 K . As the MCE in (I) exceeds that of the commercial magnetic refrigerant GGG $\left(\mathrm{Gd}_{3} \mathrm{Ga}_{5} \mathrm{O}_{12},-\Delta S_{\mathrm{m}}=24 \mathrm{~J} \mathrm{~kg}^{-1} \mathrm{~K}^{-1}, \Delta H=30 \mathrm{kG}\right), \mathrm{CP}$ (I) can be regarded as a potential cryogenic material for low-temperature magnetic refrigeration.

## 1. Introduction

Coordination polymers (CPs), a class of compounds based on repetition of metal cations connected by coordinated linkers, have developed rapidly in the past 20 years (Chakraborty et al., 2021) due to their interesting structures and variable applications in gas storage and separation (Roztocki et al., 2020), catalysis (Kang et al., 2019), sensing (Lustig et al., 2017) and magnetic materials (Yang et al., 2019a). In particular, due to the unique $4 f$ electron configuration of $\mathrm{Ln}^{3+}$ ions, lanthanide coordination polymers (Ln-CPs) usually exhibit a high coordination number, flexible coordination geometry and strong spin-orbit coupling (Sorace et al., 2011; Liu et al., 2016). These properties suggest their application in luminescence sensing (Ye et al., 2017), molecular magnetism (Liu et al., 2019), magnetic resonance imaging (Debroye \& Parac-Vogt, 2014) and related fields (Kumar et al., 2019).

Magnetic refrigeration represents a focus area in the field of magnetism. This approach is based on the magnetocaloric effect (MCE) (Yang et al., 2015; Wu et al., 2021) and is considered a highly efficient and energy-saving, hence environmentally friendly, technology. Key factors for success comprise a high-spin ground state $S$, negligible magnetic
anisotropy and low-lying excited spin states (Evangelisti et al., 2006; Liu et al., 2014a). The basic principle of magnetic refrigeration is realized through repeated cycles of isothermal magnetization and adiabatic demagnetization through the MCE displayed by the magnetic materials (Han et al., 2018). Magnetic refrigeration has potential for the generation of ultra-low temperatures. The magnitude of the MCE is usually measured by magnetic entropy change $\left(-\Delta S_{\mathrm{m}}\right)$ and adiabatic temperature change ( $\Delta T_{\text {ad }}$ ) under certain conditions (Franco et al., 2018). A large $\Delta S_{\mathrm{m}}$ under a relatively low magnetic field is mandatory for an attractive cryogenic magnetorefrigerant (Liu et al., 2017). The $-\Delta S_{\mathrm{m}}$ value of the well-known commercial low-temperature magnetic refrigeration material GGG $\left(\mathrm{Gd}_{3} \mathrm{Ga}_{5} \mathrm{O}_{12}\right)$ is $24 \mathrm{~J} \mathrm{~kg}^{-1} \mathrm{~K}^{-1}(\Delta H=30 \mathrm{kG})$ (Daudin et al., 1982).

Scheme 1
The $\mathrm{Gd}^{3+}$ ion meets the requirements of a high-spin ground state $S(S=7 / 2)$, of low-lying excited spin states and magnetic isotropy (Niu et al., 2019). The magnetic coupling between $\mathrm{Gd}^{3+}$ centres is relatively weak, which allows the system to achieve a large MCE (Zhang et al., 2021). Therefore, the $\mathrm{Gd}^{3+}$ ion represents an ideal choice for the construction of mol-ecular-based low-temperature magnetic refrigeration materials (Wang et al., 2019). At present, molecular materials of cryogenic magnetic refrigeration mainly include Gd-based

clusters and Gd-based CPs. However, the exploration of MCE for one-dimensional (1D) linear $\mathrm{Gd}^{3+} \mathrm{CPs}$ has only rarely been documented (Liu et al., 2014b).

In view of the above-mentioned promising properties, we report the new two-dimensional (2D) $\mathrm{Gd}^{3+}$ complex, [Gd(Habtc) $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]_{n}$, (I), for which we selected azobenzene$2,2^{\prime}, 3,3^{\prime}$-tetracarboxylic acid $\left(\mathrm{H}_{4}\right.$ abtc $)$ as the ligand. The four carboxylic acid groups of this rigid $\mathrm{H}_{4}$ abtc linker may be partially or completely deprotonated and thus show flexible and diverse coordination patterns. In one of these coordination modes, the O atoms of a carboxylate group can bridge $\mathrm{Gd}^{3+}$ ions and thus ensure magnetic exchange and transfer between adjacent $\mathrm{Gd}^{3+}$ ions, at the same time maintaining an overall rigid product (Zhang et al., 2015c). In this article, we communicate the synthesis, structure and magnetic properties of (I).

## 2. Experimental

All reagents and solvents used were commercially available and were used without further purification. $\mathrm{H}_{4}$ abtc was purchased from Jinan Trading Company (China). FT-IR spectra were obtained with a Bruker TENSOR27 spectrometer on KBr disks in the $4000-400 \mathrm{~cm}^{-1}$ region. Elemental analyses (EAs) were performed using a PerkinElmer 240 elemental analyzer. Powder X-ray diffraction (PXRD) data were collected on a Bruker D8 Advance X-ray diffractometer $(\mathrm{Cu} \mathrm{K} \mathrm{\alpha}, \lambda=1.5418 \AA)$ at a rate of $10^{\circ} \mathrm{min}^{-1}$ in the $2 \theta$ range
$5-50^{\circ}$. Based on the results of the single-crystal X-ray diffraction experiment, the simulated pattern was obtained with Mercury (Macrae et al., 2020) assuming $\mathrm{Cu} \mathrm{K} \alpha_{1}$ radiation ( $\lambda=$ $1.54056 \AA$ ). The thermogravimetric analysis was performed on a Dupont thermal analyzer between room temperature and 1045 K under an $\mathrm{N}_{2}$ flow with a heating rate of $10 \mathrm{~K} \mathrm{~min}^{-1}$. Magnetic susceptibility was measured from a microcrystalline sample using a SQUID magnetometer (Quantum Design MPMS) in the range $2-300 \mathrm{~K}$ with a direct-current field of 1000 Oe. Isothermal field-dependent magnetization $M(H)$ was measured in the range $0-7 \mathrm{~T}$ from 2 to 10 K .

### 2.1. Synthesis and crystallization

The reaction route to (I) is shown in Scheme 1. $\mathrm{Gd}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}(67.7 \mathrm{mg}, 0.15 \mathrm{mmol})$ and $\mathrm{H}_{4}$ abtc $(35.8 \mathrm{mg}$, 0.1 mmol ) were dissolved in a mixture of $N, N$-dimethylformamide (DMF, 2 ml ), acetonitrile $\left(\mathrm{CH}_{3} \mathrm{CN}, 2 \mathrm{ml}\right)$ and distilled water $\left(\mathrm{H}_{2} \mathrm{O}, 6 \mathrm{ml}\right)$. The solution was sealed in a stainless steel container and heated under autogenous pressure at 393 K for 72 h . After this period, heating was suspended and the container was allowed to cool to room temperature. Yellow block-shaped crystals of the product were obtained by filtration, washed with water and dried in the air (yield 67\%). Analysis calculated (\%) for $\mathrm{C}_{16} \mathrm{H}_{11} \mathrm{GdN}_{2} \mathrm{O}_{10}$ : C 35.01, H 2.01, N 5.10; found: C 35.05, H 2.02, N 5.13 .

### 2.2. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 1. Carbon-bound H atoms were placed in calculated positions and refined using a riding model, with aromatic $\mathrm{C}-\mathrm{H}=0.93 \AA$ and $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$. The water H -atom positions were fixed as found $(\mathrm{O}-\mathrm{H}$ distances are approximately $0.82 \AA$ ), with $U_{\text {iso }}(\mathrm{H})=1.5 U_{\text {eq }}(\mathrm{O})$. A difference Fourier map (Fig. 1) suggested Wyckoff position $4 b$ for atom $\mathrm{H} 4 A$ in the short $\mathrm{O} \cdots \mathrm{O}$ contact, albeit as a very broad residual electron-density maximum. Our structure model with H 4 in this special position therefore assumes a

Figure 2
IR spectra of the ligand and (I).
short symmetric hydrogen bond. In the absence of highresolution or neutron data, we can neither disprove nor support a split-atom alternative and an asymmetric hydrogen bond. Şerb et al. (2011) have compiled structures featuring very short $\mathrm{O} \cdots \mathrm{O}$ bonds. The reflection conditions for the correct space group $C 2 / c$ are also compatible with the subgroup $C c$; tentative refinements in this noncentrosymmetric subgroup resulted in numerous high correlations and anticorrelations for positional and displacement parameters: 26 elements of the final inverted refinement matrix showed correlation coefficients with a modulus $>0.9$ and more than 100 with a modulus $>0.8$. These high correlations resulted in an unrealistically broad range of $\mathrm{C}-\mathrm{C}$ bonds, and no convergence for physically meaningful displacement parameters could be achieved.

## 3. Results and discussion

### 3.1. IR spectroscopy

The IR spectra of the ligand and (I) in the range 4000$400 \mathrm{~cm}^{-1}$ are presented in Fig. 2. The broad band at $3405 \mathrm{~cm}^{-1}$ indicates $\mathrm{O}-\mathrm{H}$ stretching of the hydroxy groups and the coordinated water molecules in (I) (Yang et al., 2019b). The characteristic absorption peaks of the asymmetric and symmetric stretching vibrations of the carboxylate groups appear at 1383 and $1563 \mathrm{~cm}^{-1}$ for (I) (Du et al., 2016; Li et al., 2012; Zhang et al., 2015a). They are clearly shifted to lower wavenumbers in comparison with free $\mathrm{H}_{4}$ abtc (1426 and $1572 \mathrm{~cm}^{-1}$ ), suggesting that the carboxylate groups in the complex are coordinated to the $\mathrm{Gd}^{3+}$ ions (An et al., 2018). The absorption observed at $1468 \mathrm{~cm}^{-1}$ is caused by the $\mathrm{N}=\mathrm{N}$ stretching vibration of the ligand (Goel \& Kumar, 2018). The structural features of the complex deduced from IR spectra match the results of the single-crystal X-ray analysis. IR (KBr, $v, \mathrm{~cm}^{-1}, s=$ strong, $m=$ medium and $w=$ weak): $3405(m), 1709$ (w), 1563 (s), 1468 (s), 1383 (s), 1298 (w), 1147 (w), 1072 (m), $934(w), 840(m), 769(s), 684(w), 571(s), 500(s)$.

### 3.2. Structure description

Coordination polymer (I) crystallizes in the monoclinic space group $C 2 / c$, adopting a 2 D framework based on coordination and covalent bonds; we originally expected a threedimensional (3D) solid from the reaction between $\mathrm{Gd}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{H}_{4}$ abtc. The asymmetric unit of (I) contains a $\mathrm{Gd}^{3+}$ ion situated on a twofold axis (Wyckoff position $4 e$ ), one half of the Habtc ${ }^{3-}$ ligand and a coordinated $\mathrm{H}_{2} \mathrm{O}$ molecule. As shown in Fig. 3, each $\mathrm{Gd}^{3+}$ ion is eightcoordinated by O atoms in a $\left\{\mathrm{GdO}_{8}\right\}$ environment, in which six O atoms [O1, O2, O3, $\mathrm{O}^{1}$, $\mathrm{O} 2^{\mathrm{i}}$ and $\mathrm{O} 3^{\mathrm{i}}$; symmetry code: (i) $-x,-y+1,-z+1]$ are derived from the carboxylate groups of four Habtc ${ }^{3-}$ moieties and two O atoms ( O 5 and $\mathrm{O} 5^{\mathrm{i}}$ ) represent aqua ligands. The $\mathrm{Gd}-\mathrm{O}$ distances are in the range 2.3449 (15) -2.4503 (16) $\AA$ and the $\mathrm{O}-\mathrm{Gd}-\mathrm{O}$ angles vary from 68.66 (5) to $149.37(5)^{\circ}$ (Table 2), consistent with values observed in related compounds (Nakamura et al., 2021). The coordination polyhedron about the $\mathrm{Gd}^{3+}$ ion displays a

Symmetry code: (i) $-x, y,-z+\frac{1}{2}$.
dicapped trigonal prismatic geometry, in which each Habtc ${ }^{3-}$ links four $\mathrm{Gd}^{3+}$ ions in a $\mu_{4}-\eta^{1}: \eta^{1}: \eta^{1}: \eta^{0}: \eta^{1}: \eta^{1}: \eta^{1}: \eta^{0}$ coordination mode and all $\mathrm{Gd}^{3+}$ ions are connected via four bridging Habtc ${ }^{3-}$ ligands. Adjacent $\mathrm{Gd}^{3+}$ atoms are linked by the carboxylate groups of $\mathrm{Habtc}^{3-}$, forming a linear Gd chain along [010]; the Gd $\cdots$ Gd separation corresponds to the lattice parameter $b$ of 5.0236 (9) $\AA$ [Fig. 4(a)]. The 1D Gd chains are bridged by the central azo group of the Habtc ${ }^{3-}$ ligands to form a layer structure [Fig. 4(b)]. Two Habtc ${ }^{3-}$ ligands share the proton H 4 which is located on a centre of inversion [see Refinement ( $\$ 2.2$ ) and Fig. 1] and plays the decisive role in linking adjacent coordination layers to a 3D framework [Fig. 4(c)]. In addition to this very short and symmetric hydrogen bond, the aqua ligand O 5 acts as a hydrogen-bond donor towards carboxylate O atoms of a neighbouring layer. Detailed information of the intermolecular hydrogen bonds is summarized in Table 3. In order to obtain better insight into the nature of the intricate structure of $\mathrm{CP}(\mathrm{I})$, the network was simplified and its topology was analyzed with the help of the program TOPOS (Blatov \& Shevchenko, 2006). As shown in Fig. 4(d), each Habtc ${ }^{3-}$ ligand can be perceived a four-

connected node towards $\mathrm{Gd}^{3+}$ ions and, vice versa, each $\mathrm{Gd}^{3+}$ ion is coordinated by four Habtc ${ }^{3-}$ ligands. The overall network can thus be described as a 4 -connected net with the point symbol $\left(4^{4} \cdot 6^{2}\right)$.

### 3.3. Powder X-ray diffraction (PXRD) and thermal stability

To verify the phase purity of the compound, the as-synthesized samples were characterized by PXRD at room temperature. As shown in Fig. 5(a), the experimental PXRD pattern of (I) is in excellent agreement with the simulated one, demonstrating the phase purity of the bulk sample. Minor differences in line intensities can probably be attributed to preferred orientation of the powder sample. Thermal stability was investigated by a thermogravimetric analysis (TGA) under an $\mathrm{N}_{2}$ atmosphere. Fig. 5(b) summarizes the weight loss for (I) between room temperature and 1045 K . In the temperature range $325-471 \mathrm{~K}$, the TGA curve shows a weight loss of $6.88 \%$ which may be attributed to the elimination of two coordinated water molecules (calculated 6.56\%). At higher temperatures, the framework of (I) gradually collapses.

### 3.4. Magnetic properties

Magnetic properties of (I) were studied in order to understand potential magnetic interactions. Variable-temperature magnetic susceptibility measurements of (I) were conducted in the range $2-300 \mathrm{~K}$ with an applied magnetic field of 1000 Oe. As shown in Fig. 6, the experimental $\chi_{\mathrm{m}} T$ value for (I) amounts to $8.00 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$ at 300 K , close to the expected value of $7.88 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$ calculated for an isolated $\mathrm{Gd}^{3+}$ ion ( $S=7 / 2, g=2$ ) (Xi et al., 2020). As the temperature is decreased, the $\chi_{\mathrm{m}} T$ value of (I) decreases slowly to $7.93 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$ around 10 K , and then increases gradually to $8.14 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$ at 2 K . The data in the whole temperature range $2-300 \mathrm{~K}$ fit well the Curie-Weiss law with $C=$ $8.06 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}$ and $\theta=-0.08 \mathrm{~K}$. The negative $\theta$ value indicates the existence of weak antiferromagnetic interactions between the metal centres in the 1D chain of (I). To further quantitatively analyze the magnetic interactions, the molar susceptibility of (I) can be described by a Fisher expression for a classical spin chain which allows an evaluation of the magnetic coupling $(J)$ between adjacent $\mathrm{Gd}^{3+}$ ions (Farger et al., 2018). The best least-squares fit parameters are $g=2.01$ and $J=$ $-0.02 \mathrm{~cm}^{-1}$, with an agreement factor $R=6.27 \times 10^{-5}$ in the range $35-300 \mathrm{~K}$. The value for $J$ further proves the existence of weak antiferromagnetic interactions between adjacent $\mathrm{Gd}^{3+}$ ions in (I).

Figure 4
(a) Distances between adjacent $\mathrm{Gd}^{3+}$ ions in the 1D metal chain constructed by $\mathrm{Gd}^{3+}$ ions and the carboxylate groups of the Habtc ${ }^{3-}$ ligands $(\mathrm{H}$ atoms have been omitted for clarity). (b) The 2D layer of (I). The inset is the local coordination geometry of the Gd ${ }^{3+}$ ion of (I). [Symmetry code: (i) $-x, y$, $-z+\frac{1}{2}$.] (c) The 3D framework formed by hydrogen bonds in (I) (different colours represent different layers and $\mathrm{H} 4 A$ atoms are shown in red). (d) The 2D topology of (I) with point symbol $\left(4^{4} \cdot 6^{2}\right)$.

The magnetization of (I) was measured in the interval between 0 and 7 T at temperatures between 2 and 10 K (Fig. 7a). The $M$ values for (I) show a steady increase with
increasing $H$ and a saturation value of $7.14 \mathrm{~N} \beta$ at 7 T and 2 K , which is close to the expected value of $S \times g=7 / 2 \times 2=7 \mathrm{~N} \beta$ for an isolated $\mathrm{Gd}^{3+}$ ion ( $S=7 / 2, g=2$ ). To evaluate the magne-

tocaloric effect (MCE), the magnetic entropy change $\left(-\Delta S_{\mathrm{m}}\right)$ of (I) was calculated for a field between 0 and 7 T in the temperature range $2-10 \mathrm{~K}$, and it can be obtained (Fig. $7 b$ ) by the Maxwell relation in the equation $\Delta S_{\mathrm{m}}(T)=[M(T, H) /$ $T]_{H} \mathrm{~d} H$. The resulting maximum value of $-\Delta S_{\mathrm{m}}$ amounts to $27.26 \mathrm{~J} \mathrm{~kg}^{-1} \mathrm{~K}^{-1}$ for $\Delta H=7 \mathrm{~T}$ at 3.0 K , which is smaller than the theoretical value of $31.52 \mathrm{~J} \mathrm{~kg}^{-1} \mathrm{~K}^{-1}$, as calculated from the equation $-\Delta S_{\mathrm{m}}=N_{\mathrm{Gd}} R \ln (2 s+1) / M_{\mathrm{W}}$, with $S=7 / 2$. In this equation, $M_{\mathrm{W}}$ is the formula mass of $548.52 \mathrm{~g} \mathrm{~mol}^{-1}$ and $N_{\mathrm{Gd}}$ is the number of $\mathrm{Gd}^{3+}$ ions present per mole of (I). The difference in $-\Delta S_{\mathrm{m}}$ between the theoretical and experimental values may be attributed to the existence of antiferromagnetic interactions between $\mathrm{Gd}^{3+}$ ions. The experimental $-\Delta S_{\mathrm{m}}$

Figure 6
Plots of $\chi_{\mathrm{m}}, \chi_{\mathrm{m}} T$ and $\chi_{\mathrm{m}}{ }^{-1}$ (inset) as functions of $T$ for (I). Red solid lines represent best fits.
value is also smaller than several previously prepared 1D linear-chain $\mathrm{Gd}^{3+}$ complexes (Table 4), which can be ascribed to the large $M_{\mathrm{W}} / N_{\mathrm{Gd}}$ ratio arising from the large $\mathrm{H}_{4}$ abtc ligand and the antiferromagnetic interactions between the neighbouring $\mathrm{Gd}^{3+}$ ions in (I).

### 3.5. Conclusion

In summary, the novel coordination polymer (I) has been successfully constructed under hydrothermal conditions via the combination of $\mathrm{Gd}^{3+}$ ions and the $\mathrm{H}_{4}$ abtc linker. The underlying structural principles in (I) comprise a 1D $\left[\mathrm{Gd}_{2}(\mathrm{COO})_{4}\right]_{n}$ chain and the linking of neighbouring chains via the organic ligand into a 2D structure with point symbol $\left(4^{4} \cdot 6^{2}\right)$. Further crosslinking into a 3D framework occurs via very short hydrogen bonds. The new CP offers potential for application; magnetic studies reveal that (I) displays intrachain antiferromagnetic Gd•Gd coupling and a cryogenic MCE with the maximum $-\Delta S_{\mathrm{m}}$ of $27.26 \mathrm{~J} \mathrm{~kg}^{-1} \mathrm{~K}^{-1}$ for $\Delta H=$ 7 T at 3.0 K . This small $-\Delta S_{\mathrm{m}}$ value can be ascribed to the high $M_{\mathrm{W}} / N_{\mathrm{Gd}}$ ratio arising from the large $\mathrm{H}_{4}$ abtc ligand and the antiferromagnetic interactions between neighbouring $\mathrm{Gd}^{3+}$ ions in (I). The selection of low molecular-weight ligands that transfer weak coupling may be a promising approach for obtaining $\mathrm{Gd}^{3+}$ complexes as molecule-based magnetic refrigerants. Further studies on $\mathrm{Gd}^{3+}$ complexes for magnetic refrigeration are underway in our laboratory.

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
Refinement. Single-crystal X-ray diffraction data for (I) were collected on a Bruker APEXII diffractometer equipped with 1 K CCD instrument, using a graphite monochromator with $M o K \alpha$ radiation $(\lambda=0.71073 \AA$ ) at room temperature. Absorption corrections were performed via the SADABS program (Bruker, 2001). All the structures were solved by means of direct methods with SHELXS-97 program (Sheldrick, 2008) and refined on $F^{2}$ with full-matrix least-squares techniques using the program SHELXL-2014 program (Sheldrick, 2015). All non-H atoms were refined anisotropically. H positions and isotropic displacement parameters constrained; H4a with refined Uiso on center of symmetry, hence coordinates fixed
