In the title compound, $2C_6H_{10}N_2^{2+}\cdot P_4O_{12}^{4-}$, which involves a doubly protonated 3-ammoniomethylpyridinium cation and a cyclotetraphosphate anion, the cyclotetraphosphoric ring is arranged around an inversion center and the organic entity alternates with it, forming hybrid ribbons parallel to the b axis. The crystal structure is stabilized by a three-dimensional network of N—H$\cdots$O and weaker C—H$\cdots$O hydrogen bonds.

Related literature

For properties of hybrid materials, see: Aakeröy *et al.*(1989); Sankar *et al.* (1993); Teraski *et al.* (1987); Vaughan (1993); Centi (1993); Ozin (1992). For related structures containing phosphoric acid rings, see: Aloui *et al.* (2003); Hemissi *et al.* (2005); Averbuch-Pouchot & Durif (1991); Durif (1995). For bond lengths in pyridine, see: Bak *et al.* (1959). For hydrogen bonding, see: Blessing (1986); Brown (1976); Soumhi & Jouini (1996). Cyclotetraphosphoric acid was produced from $Na_4P_4O_{12}\cdot4H_2O$, which was prepared according to the Ondik (1964) process.

Bis(3-ammoniomethylpyridinium) cyclotetraphosphate

Hanène Hemissi, Mohammed Rzaigui and Salem S. Al-Deyab

S1. Comment

Hybrid materials with organic and inorganic components continue to be a focus area in solid state chemistry and material sciences due to their potential applications in various fields, such as nonlinear optics (Aakeröy *et al.*, 1989), heterogeneous catalysis (Centi, 1993), photochemical and photophysical process (Ozin, 1992), molecular sieves (Vaughan, 1993), ceramic precursors (Sankar *et al.*, 1993) and other areas that include electronic materials (Teraski *et al.*, 1987). In the present paper, the results of the x-ray structure analysis of a new organic cyclotetraphosphate, bis(3-ammoniomethylpyridinium) cyclotetraphosphate, are discussed with respect to the geometry and flexibility of the cyclo-tetraphosphate ring system and H-bonding interactions between the inorganic acceptor and the organic donor molecules.

The chemical composition of the title compound (I) includes two fundamental entities, the $P_4O_{12}^{4-}$ ring and the organic cations $(C_6H_{10}N_2)^{2+}$. The geometrical configuration of these entities is depicted in Figure 1, while the complete atomic arrangement is shown in Figure 2. This latter shows that the crystal structure of $(C_6H_{10}N_2)_2P_4O_{12}$ can be described by hybrid ribbons where the organic and inorganic species are alternated. These ribbons, extended in the *b*-direction, are also connected between them in the two other directions via H-bonds to develop a three-dimensional network. The P_4O_{12} rings are located around the inversion center (0, 0, 0) and are built up by only two independent PO_4 tetrahedra. The P—P—P angles are 84.43 (1) and 95.57 (1)° and show that the tetramembered phosphoric rings are distorted in comparison with the ideal value (90°). It should be noted that such deviations are commonly observed in cyclotetraphosphoric ring anions with low internal symmetry as (I) (Aloui *et al.*, 2003; Hemissi *et al.*, 2005). Nevertheless, this distortion is comparatively less important than that observed in the hexamembered P_6O_{18} rings (93.2 - 145.5°) (Averbuch-Pouchot & Durif, 1991). Consequently, P_4O_{12} is less flexible than the P_6O_{18} what could explain the pronounced distortion observed for the big rings compared with their smaller rings analogues. In spite of this distortion, the examination of the main geometrical feature of PO_4 tetrahedra (P—O distances and P—O—P angles) shows that they are in accordance with values generally observed in condensed phosphates (Durif, 1995).

One crystallographically independent organic group exists in the asymmetric unit. Inside this organic molecule, both nitrogen atoms are protonated and so it is formulated $(C_6H_{10}N_2)^{2+}$. The examination of pyridinium ring shows that this unit is essentially planar with mean deviation of ±0.0036 Å from least-square plane defined by the six constituent atoms. The average C—N distances in pyridinium ring is 1.337 (2) Å and of the C—C bond lengths is 1.384 (2) Å. The latter value, being shorter than 1.39-1.41 Å, reported for non-substituent pyridine, may indicate some aromatic bond characters (Bak *et al.*, 1959). The pyridinium ring is non coplanar with its methylamine substituent (-CH_2—NH_3) which is evidenced by the torsion angle value of (C1—C2—C6—N2) equal to 96.29 (2)°. In addition to electrostatic and van der Waals interactions, the structure is further stabilized with a three-dimensional network of N—H⋯O and the weaker C—H⋯O hydrogen bonds (Table 1, Fig. 2)). In the hydrogen-bond scheme two main points should be noticed: (i) there is a bridging oxygen atom (O4) of the P_4O_{12} ring involved in hydrogen bond and so that is rarely observed in organic condensed phosphates. Indeed, it was only observed in $(C_6H_{10}N_2)_2P_4O_{12}.2H_2O$ (Soumhi *et al.*, 1996). (ii) Inside the structure, there

are two strong hydrogen bonds with N···O distances equal to 2.629 (2) and 2.708 (2) Å. The others are weaker within N(C)···O distances falling from 2.735 (2) to 3.381 (2) Å (Brown, 1976; Blessing, 1986).

S2. Experimental

Crystals of the title compound were prepared by adding ethanolic solution (5 ml) of 3-aminopicolamine (11.04 mmol) dropwise to an aqueous solution of cyclotetraphosphoric acid (5.52 mmol, 20 ml). Good quality of colourless prisms were obtained after a slow evaporation during few days at ambient temperature. The cyclotetraphosphoric acid $H_4P_4O_{12}$, was produced from $Na_4P_4O_{12}.4H_2O$, prepared according to the Ondik process (Ondik, 1964), through an ion-exchange resin in H-state (Amberlite IR 120).

S3. Refinement

All H atoms were positioned geometrically and treated as riding on their parent atoms, [N–H = 0.89, C–H =0.96 Å (CH_3) with with $U_{iso}(H) = 1.5U_{eq}$ and C–H =0.96 Å (Ar–H), with $U_{iso}(H) = 1.5U_{eq}$]

Figure 1

An ORTEP view of (I) with the atom-labelling scheme. Displacement ellipsoids are drawn at the 30% probability level. H atoms are represented as small spheres of arbitrary radii. [Symmetry codes: (i) 1 - x, 1 - y, 1 - z].

Refinement

Refinement on F^2	Primary atom site location: structure-invariant direct methods
Least-squares matrix: full	Secondary atom site location: difference Fourier map
$R[F^2 > 2\sigma(F^2)] = 0.034$	Hydrogen site location: inferred from neighbouring sites
$wR(F^2) = 0.101$	H-atom parameters constrained
$S = 1.08$	
5005 reflections	
145 parameters	
0 restraints	

$w = 1/[\sigma^2(F_o^2) + (0.049P)^2 + 0.1514P]$
where $P = (F_o^2 + 2F_c^2)/3$
$(\Delta/\sigma)_{max} = 0.001$

$\Delta\rho_{max} = 0.49$ e Å^{-3}
$\Delta\rho_{min} = -0.47$ e Å^{-3}

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted *R*-factor wR and goodness of fit *S* are based on F^2, conventional *R*-factors *R* are based on *F*, with *F* set to zero for negative F^2. The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating *R*-factors(gt) etc. and is not relevant to the choice of reflections for refinement. *R*-factors based on F^2 are statistically about twice as large as those based on *F*, and *R*- factors based on ALL data will be even larger.
