Received 6 January 2012; accepted 26 January 2012

 Key indicators: single-crystal X-ray study; $T = 123$ K; mean $\sigma(\text{C}-\text{C}) = 0.007$ Å; R factor = 0.021; wR factor = 0.045; data-to-parameter ratio = 17.8.

In the title compound, $[\text{HgCl}_2(\text{C}_{12}\text{H}_{19}\text{N}_3)]$, the Hg^{II} ion is coordinated by three N atoms of the (1*R*,2*R*)-*N*-(pyridin-2-ylmethyl)cyclohexane-1,2-diamine ligand and by a Cl atom in the basal plane, and by a second Cl atom in the apical position, within a distorted square-pyramidal geometry. The coordination of the enantiopure ligand to the metal atom renders the central N atom chiral with an *S* configuration, so the complex is enantiomerically pure and corresponds to the *S,R,R* diastereoisomer. Molecules are linked *via* weak $\text{N}-\text{H}\cdots\text{Cl}$ hydrogen bonds into a one-dimensional hydrogen-bonding supramolecular chain along the crystallographic *b* axis.

Dichlorido[(1*R*,2*R*)-*N*-(pyridin-2-ylmethyl)cyclohexane-1,2-diamine- κ^3 *N,N',N''*]mercury(II)**Chuan-Zhu Gao, Xiu-Ying Zhang and Lin Cheng****S1. Comment**

Recently, there has been current significant interest in the rational design and synthesis of chiral coordination polymers due to their potential utility in enantiomerically selective catalysis and separations, second-order non-linear optical applications and luminescence (He *et al.* 2010). A basic design route for this kind of polymers is to appropriately organize the metal ions into ordered architectures by use of chiral ligands. Herein, we report a new chiral complex, Hg(2-*Amp*)Cl₂, where 2-*Amp* = 2-(((1*R*,2*R*)-2-aminocyclohexylamino)methyl)phenol, as a chiral ligand.

The title compound is a mononuclear complex, in which the coordination environment of Hg^{II} can be described as distorted square-pyramidal, being surrounded by one tridentate ligand and two chlorine anions (Fig. 1).

The molecules are linked to each other, *via* weak N—H···Cl hydrogen bonds, into a one-dimensional hydrogen bonding network (Table 1, Fig. 2).

S2. Experimental

(1*R*,2*R*)-*N*¹-(pyridin-2-yl-methyl)cyclohexane-1,2-diamine (0.041 g, 0.2 mmol) dissolved in water (8 ml) was added to a methanol solution (10 ml) of HgCl₂ (0.054 g, 0.2 mmol). The mixture solution was stirred for 1 h at room temperature and then filtered. The filtrate was allowed to evaporate slowly at room temperature. After 2 weeks, colourless block crystals were obtained with 58.7% yield (0.056 g).

S3. Refinement

All H atoms attached to C atoms were fixed geometrically and treated as riding with C—H = 0.95–1.00 Å with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$. H atoms attached to N atoms were located in difference Fourier maps and included in the subsequent refinement using restraints with N—H = 0.87 Å with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{N})$.

Figure 1

View of the title compound with the atom-labelling scheme. Displacement ellipsoids are drawn at the 30% probability level. H atoms are represented as small spheres of arbitrary radii.

Figure 2

Special details

Geometry. All s.u.'s (except the s.u. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell s.u.'s are taken into account individually in the estimation of s.u.'s in distances, angles and torsion angles; correlations between s.u.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell s.u.'s is used for estimating s.u.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
