Received 23 January 2012; accepted 7 February 2012

Key indicators: single-crystal X-ray study; $T = 296$ K; mean $\sigma(\text{C}-\text{C}) = 0.005$ Å; R factor = 0.062; wR factor = 0.200; data-to-parameter ratio = 14.0.

In the centrosymmetric title compound, $\text{C}_{12}\text{H}_{10}\text{O}_2\text{S}_2$, the alkyl chains adopt a fully extended all-*trans* conformation with respect to the C(thiophene)–C bond. The non-H atoms of the molecule are nearly planar, with a maximum deviation of 0.063 (2) Å from the mean plane of the constituent atoms. In the crystal, symmetry-related molecules are linked *via* pairs of C–H $\cdots\pi$ contacts [H–centroid distances of the thiophene units = 2.79 (9) and 2.82 (4) Å], in turn interdigitating with each other along the *bc* plane, thus leading to an interwoven two-dimensional network.

1,4-Bis(thiophen-2-yl)butane-1,4-dione

Wei-Ting Guo, Zhi-Min Miao and Yun-Long Wang

S1. Comment

Electroactive and photoactive thiophene-based molecules, oligomers, and polymers (Atalar *et al.*, 2009; Chen *et al.*, 2009; Charati *et al.*, 2008; Becerra *et al.*, 2010; Liu *et al.*, 2008; Nair, Devipriya & Eringathodi, 2007; Nair, Vellalath *et al.*, 2007; Bushueva *et al.*; 2010) are important for advanced technological applications, including display technologies, field-effect transistors, solar cells, sensors, nonlinear optics, molecular wires, and diodes (Cao *et al.*, 2008; Wu *et al.*, 2008). Thiophenes and its derivatives are originally applied to synthesize thiophene-based compounds, such as, oligomers and polythiophenes due to easy electropolymerization of thiophenes to produce stable, electrically conductive polymeric films. Thiophenes and its derivatives can also be widely used as building blocks in many agrochemicals and pharmaceuticals. To investigate the relationship between structure and pharmacological activity, the title compound was synthesized and its structure was determined by X-ray diffraction. As shown in figure 1, the centrosymmetric title compound lies across a crystallographic inversion centre which is situated at the midpoint of the C6–C6A (1.512 (8) Å, symmetry code: (A) 2-x, 1-y, 1-z) bond. The alkyl chains attached thiophenes adopt a fully extended all-*trans* conformation with respect to the C_{thiophene}–C bond. The non-H atoms of the molecule is nearly planar with O1 and O1A maximum deviation of 0.063 (2) Å from the mean plane of its constituting atoms. The C1–S1 and C4–S1 bond length of 1.678 (5) and 1.697 (4) Å, respectively, correspond to typical single C–S bonds. Whereas the C1–O1 (1.215 (5) Å) bond length indicate the presence of a typical double C=O bond (Allen *et al.*, 1987). It is well-established that weak bonding interactions between entities, such as hydrogen-bonding and π -stacking, are important supramolecular forces, which can be used to govern the process of molecular recognition and selfassembly (Hu *et al.*, 2008; Ishihara *et al.*, 2007; Jennings *et al.*, 2001). In the crystal structure, it is noteworthy that symmetry-related molecules, in turn, are linked *via* pairs of intermolecular C–H $\cdots\pi$ contacts [H–centroid distance of the thiophene units = 2.79 (9) - 2.82 (4) Å], and interdigitated with each other along *bc* plane, thus leading to an interwoven two dimensional network.

S2. Experimental

Reagents and solvents were of commercially available quality. The title compound was synthesized according to the method of Schweiger *et al.* 2000. To a suspension of AlCl₃ (16 g, 0.12 mol) in CH₂Cl₂ (15 ml) a solution of thiophene (10 ml, 0.12 mol) and succinyl chloride (6 ml, 0.05 mol) in CH₂Cl₂ was added dropwise. The red mixture was stirred at r.t. for 18 h. This was then quenched with ice and conc. HCl (5 ml). After intensive stirring for 2 h the dark green organic phase was separated, washed with 2 M HCl, H₂O NaHCO₃ solution and dried over MgSO₄. After evaporation of the solvent a blue-green solid remained, which was suspended in ethanol. Filtration and washing with ethanol and diethyl ether provided a green solid. Column chromatography (SiO₂, CH₂Cl₂-hexane (1 : 1)) obtains (I) as a white solid 6.74 g (26.87 mmol; 54%). Single crystals suitable for X-ray diffraction were prepared by slow evaporation of a solution of the crude (5 g) in a mixture of water/ethanol (20 ml, 1:1, *v/v*) at room temperature.

S3. Refinement

All H atoms were placed in idealized positions ($C-H = 0.93-0.97 \text{ \AA}$) and refined as riding atoms with $U_{iso}(H) = 1.2U_{eq}(C)$.

Figure 1

The molecular structure of the title compound, with displacement ellipsoids at the 30% probability level (Symmetry code: (A) $2-x, 1-y, 1-z$).

Figure 2

The $C-H \cdots \pi$ stacking interactions (dashed lines) in the structure of the title compound viewing along bc plane, H atoms have been omitted for clarity, except for those involved in $C-H \cdots \pi$ stacking interactions.

 $\Delta\rho_{\min} = -0.35 \text{ e \AA}^{-3}$

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2 , conventional R-factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\sigma(F^2)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F , and R-factors based on ALL data will be even larger.
