# Redetermination of $\left[\mathrm{Pr}\left(\mathrm{NO}_{3}\right)_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right] \cdot \mathbf{2 H} \mathbf{H}_{2} \mathrm{O}$ 

## Roel Decadt, Pascal Van Der Voort, Isabel Van Driessche, Rik Van Deun and Kristof Van Hecke*

Department of Inorganic and Physical Chemistry, Ghent University, Krijgslaan 281 - S3, B-9000 Ghent, Belgium
Correspondence e-mail: Kristof.VanHecke@UGent.be

Received 8 June 2012; accepted 20 June 2012

Key indicators: single-crystal X-ray study; $T=100 \mathrm{~K}$; mean $\sigma(\mathrm{O}-\mathrm{N})=0.003 \AA$; $R$ factor $=0.017 ; w R$ factor $=0.037$; data-to-parameter ratio $=13.2$.

The structure of the title compound, tetraaquatris(nitrato$\kappa^{2} O, O^{\prime}$ )praseodymium(III) dihydrate, was redetermined. The structure models derived from the previous determinations [Rumanova et al. (1964). Kristallografiya, 9, 642-654; Fuller \& Jacobson (1976). Cryst. Struct. Commun. 5, 349-352] were confirmed, but now with all H atoms unambiguously located, revealing a complex $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen-bonding network, extending throughout the whole structure. In the title compound, the coordination environment of the $\mathrm{Pr}^{\mathrm{III}}$ atom can best be described as a distorted bicapped square antiprism defined by three bidentate nitrate anions and four water molecules. Additionally, two lattice water molecules are observed in the crystal packing. The title compound is isotypic with several other lanthanide-containing nitrate analogues.

## Redetermination of $\left[\operatorname{Pr}\left(\mathrm{NO}_{3}\right)_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$

Roel Decadt, Pascal Van Der Voort, Isabel Van Driessche, Rik Van Deun and Kristof Van Hecke

## S1. Comment

The title compound was serendipitously obtained in low yield as an undesired product of an experiment aimed at obtaining a Pr ${ }^{\text {III-containing coordination polymer, with dicarboxylate ligands as the connecting moieties, following an }}$ earlier successful synthesis of a vanadium metal-organic framework with the same type of linkers (Liu et al., 2012).
The structure of the title compound is analogous to the structures, previously determined, with ICSD entries 22339 (Rumanova et al., 1964) and 123 (Fuller \& Jacobson, 1976) (ICSD Version 1.8.1; Bergerhoff et al., 1983; ICSD, 2009). However, in both of the latter structures, the "position of elements of H were undetermined". In the now determined structure, these hydrogen atoms could unambiguously be located from difference Fourier electron density maps, revealing an extended hydrogen bonding network.

The structure of the title compound is isotypic with other $\left[\operatorname{Ln}\left(\mathrm{NO}_{3}\right)_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ analogues, for example for $L n=\mathrm{Nd}$ (ICSD entries 37181 and 71767) (Rogers et al., 1983; Shi \& Wang, 1991), Ln $=\operatorname{Sm}$ (ICSD entry 69158) (Shi \& Wang, 1990) and $L n=E u(I C S D$ entry 280528) (Stumpf \& Bolte, 2001). Three additional Sm-analogues were reported by Kawashima et al., 2000 (ICSD entries 91511, 91512 and 91513).

The asymmetric unit consists of one $\operatorname{Pr}^{\text {III }}$ cation, three nitrate anions, and in total six water molecules. The $\operatorname{Pr}^{\text {III }}$ cation is ten-coordinated by the oxygen atoms of three bidentate nitrate anions and four water molecules. Additionally, two lattice water molecules are included in the second coordination sphere of the praseodymium cation. The coordination polyhedron around $\mathrm{Pr}^{\text {III }}$ can be best described as a distorted bicapped square antiprism (Figure 1). The $\mathrm{Pr}-\mathrm{O}$ distances range from 2.5677 (16) to 2.7307 (15) $\AA$ and from 2.4287 (17) to 2.4578 (17) $\AA$ for the coordinating nitrate groups and water molecules, respectively (Table 1). The coordinating nitrate groups are positioned on the same side of the polyhedron, whereas the coordinating water molecules are positioned on the opposite side.
When searching the Cambridge Structural Database (CSD, Version 5.33) (Allen, 2002), another Pr ${ }^{\text {III }}$-complex is found (CSD reference code VAFLOD), containing three nitrate anions and four water molecules in its coordination sphere.
However, this complex shows a totally different, approximately twofold symmetry (Weakley, 1989). Other structures of metal-organic complexes of $\mathrm{Pr}^{\text {III }}$, coordinated by only nitrate and water molecules are found, showing different coordination assemblies, i.e. a 12 -coordinated $\mathrm{Pr}^{\text {III }}$ atom with five nitrate and two aqua ligands, balanced by two additional counter ions (CSD reference code QERRIP) (Rohde \& Urland, 2006), a complex with three nitrate and three aqua ligands (CSD reference code CUKMUQ) (Weakley, 1984), and even the formation of dimers (CSD reference code BUPFIB) (Weakley, 1982) have been previously reported.
In the reported structure, a complex, extended hydrogen bonding network is formed throughout the whole structure, stabilizing the crystal packing, i.e. in total 16 different hydrogen bonds are observed between the coordinating water molecules, nitrate anions and lattice water molecules (Figure 2). In total, eight different symmetry equivalent water or nitrate oxygen atoms are involved in the hydrogen bond network. In fact, the praseodymium complexes are all interconnected through these solvent water molecule hydrogen bonds (Figure 3). The four coordinating water molecules
show the following hydrogen bonds: O 10 is hydrogen bonded to the symmetry-equivalent water molecule oxygen atom O 14 and nitrate O 8 . Water O 11 is hydrogen bonded to the symmetry equivalent waters O 14 and O 15 . Water O 12 is hydrogen bonded to the symmetry equivalent nitrate O 4 and forms an intramolecular hydrogen bond with water O15. Water O13 shows two bifurcated hydrogen bonds to the symmetry equivalent nitrates O 7 and O 9 and to O 4 and O 8 . The solvent water molecule O 14 forms an intramolecular hydrogen bond with nitrate O 9 and a bifurcated hydrogen bond to the symmetry equivalent nitrates O 3 and O 5 . Solvent water molecule O 15 forms a bifurcated hydrogen bond to two different symmetry equivalent nitrate O 3 atoms and another hydrogen bond to a symmetry equivalent nitrate O6. Details of the hydrogen-bonding geometry are given in Table 2.

## S2. Experimental

The title compound was serendipitously obtained in low yield as a product of an experiment aimed at obtaining a $\mathrm{Pr}^{\text {III }}$ containing coordination polymer, with dicarboxylate ligands as the connecting moiety, following an earlier successful synthesis of a vanadium metal-organic framework with the same type of linkers (Liu et al., 2012).
In the synthesis, $0.1 \mathrm{mmol} \operatorname{Pr}\left(\mathrm{NO}_{3}\right)_{3} \times \mathrm{xH}_{2} \mathrm{O}$, along with 0.3 mmol dicarboxylic acid and four drops of 0.6 M aqueous $\mathrm{HNO}_{3}$ was dissolved in 5 ml of a $1: 1$ mixture of $1: 1 \mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$. After seven days of heating the mixture to 363 K , the title compound was isolated as colourless crystals, suitable for single-crystal X-ray diffraction analysis.

## S3. Refinement

All hydrogen atoms were located in a difference Fourier electron density map and further refined with isotropic temperature factors fixed at 1.5 times $U_{\mathrm{eq}}$ of the parent atoms, applying a restraint value of 0.84 (2) $\AA$ for the $\mathrm{O}-\mathrm{H}$ distances.

Figure 1
Coordination geometry of the title compound, showing the atom-labelling scheme of the asymmetric unit and $60 \%$ probability displacement ellipsoids.

Figure 2

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors (gt) etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
