Received 28 June 2012; accepted 23 July 2012

Key indicators: single-crystal X-ray study; $T = 150$ K; mean $\sigma(\text{C}-\text{C}) = 0.004$ Å; R factor = 0.030; wR factor = 0.081; data-to-parameter ratio = 17.4.

The asymmetric unit of the title compound, $\text{C}_{14}\text{H}_{20}\text{Br}_2\text{O}_2$, contains one half-molecule located on an inversion centre. The molecule is essentially planar, with a maximum deviation from the best plane of the non-H atoms of 0.054 (2) Å for the O atoms. The butoxy group adopts a fully extended all-*trans* conformation. In the crystal, molecules are connected *via* C—Br \cdots O halogen bonds [Br \cdots O = 3.2393 (19) Å] into a two-dimensional corrugated network in the *bc* plane.

1,4-Dibromo-2,5-dibutoxybenzene

Chin Hoong Teh, Muhammad Mat Salleh, Mohamed Ibrahim Mohamed Tahir, Rusli Daik and Mohammad B. Kassim

S1. Comment

Dialkoxy-substituted benzenes such as the title compound (I) are very useful intermediates to synthesize soluble poly(*p*-phenylene) (Huang *et al.*, 2007; Lightowler & Hird, 2005), thiophene–phenylene co-oligomers (Promarak & Ruchirawat, 2007) and poly(phenylene vinylene) (Brandon *et al.*, 1997), which have wide range of applications in semiconductor and electronics industries.

The title compound is similar to its analog, 1,4-dibromo-2,5-bis(hexyloxy)-benzene (II) (Li *et al.*, 2008). The alkyl chains are nearly coplanar with the benzene ring, with C4—O1—C3—C2 torsion angles of 3.3 (4)°, which is similar to II. However, the title compound is stabilized by intermolecular Br⋯O interactions [3.2393 (19) Å], which has shorter distance, compared to Br⋯Br interactions (3.410 Å) found in II. The intermolecular Br⋯O interaction is shorter than the sum of the Van der Waals radii of the relevant atoms (3.37 Å) and those found in other compound [3.301 (4) Å] (Fun *et al.* 2010).

In the crystal, nearly linear halogen bond C1–Br1⋯O1(-*x*, 1/2 + *y*, 1/2 - *z*) [\angle C1–Br⋯O159.96 (9)°] link the molecules into a two-dimensional corrugated network along *bc* plane (Figure 2).

S2. Experimental

The compound was prepared according to previously published work with a slight modification (Lopez-Alvarado *et al.*, 2002). To 1,4-bis(butoxy)benzene (5.00 g, 22.5 mmol) was added dropwise Br₂ (7.55 g, 47.25 mmol) in glacial acetic acid. The mixture was stirred at room temperature for two hours followed by heating under reflux for another two hours. The mixture was left to cool to room temperature and water was then added to precipitate the product. The product was filtered, washed with excess water and 1.0 *M* sodium bicarbonate solution. Slow recrystallization of the product from methanol–ethyl acetate mixture afforded crystals suitable for single X-ray diffraction (yield: 82%).

S3. Refinement

The hydrogen atom positions were calculated geometrically and refined in a riding model approximation with C–H bond lengths in the range 0.93–0.97 Å and $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ for aromatic and CH₂ group, and $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{C})$ for methyl group.

 where $P = (F_o^2 + 2F_c^2)/3$
 $(\Delta/\sigma)_{\max} < 0.001$
 $\Delta\rho_{\max} = 0.73 \text{ e } \text{Å}^{-3}$
 $\Delta\rho_{\min} = -0.38 \text{ e } \text{Å}^{-3}$

Special details

Experimental. The crystal was placed in the cold stream of an Oxford Cryosystems open-flow nitrogen cryostat (Cosier & Glazer 1986) with a nominal stability of 0.1 K.

Cosier, J. & Glazer, A.M., (1986)., *J. Appl. Cryst.* **105** 107.

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
