# Redetermined crystal structure of $\alpha$-DL-methionine at 340 K 

Carl Henrik Görbitz,* Lianglin Qi, Ngan Thi Kim Mai and Håvard Kristiansen

Department of Chemistry, University of Oslo, PO Box 1033 Blindern, N-0315 Oslo, Norway. *Correspondence e-mail: c.h.gorbitz@kjemi.uio.no

Two forms, $\alpha$ and $\beta$, are known for the racemic amino acid DL-methionine, $\mathrm{C}_{5} \mathrm{H}_{11} \mathrm{NO}_{2} \mathrm{~S}$. The phase transition between them, taking place around 326 K , is associated with sliding at the central interfaces of the hydrophobic regions in the crystal, leaving the hydrogen-bonding pattern unperturbed. For the hightemperature $\alpha$ phase, only a structure of rather low quality has been available [ $R$ factor $=0.118$, no H-atom coordinates; Taniguchi et al. (1980). Bull. Chem. Soc. Jpn, 53, 803-804]. We here present accurate structural data for this polymorph $[R(\mathrm{~F})=0.049]$, which are compared with other related amino acid structures with similar properties. We report for the first time that the side chain of this phase has a minor disorder component [occupancy 0.0491 (18)] with a gauche+ rather than a gauche - conformation for the $\mathrm{N}-\mathrm{C}-\mathrm{C}-\mathrm{C}$ group. In the crystal of the title compound, $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds link the molecules into (100) sheets.

## 1. Chemical context

The racemates of amino acids with linear side chains display a series of unique phase transitions that involve sliding of neighboring molecular bilayers compared to each other. Such behavior has been observed for Dl-aminobutyric acid (DL-Abu, $R=-\mathrm{CH}_{2} \mathrm{CH}_{3}$; Görbitz et al., 2012), DL-norvaline (DL-Nva, $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$; Görbitz, 2011), DL-norleucine (DLNle, $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$; Coles et al., 2009) and dL-methionine (Dl-Met, $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{SCH}_{3}$ ). Two phase transitions have been found for each of the three nonstandard amino acids. For DL-Met, only a single transition is known $<400 \mathrm{~K}$, occurring at approximately 326 K from the $\beta$ (low $T$ ) to the $\alpha$ form (high $T$ ). Both phases were originally described by Mathieson (1952), with $R$ factors $>0.20$, and were subject to redeterminations by Taniguchi et al. (1980) at room temperature ( $R=$ $0.088)$ and $333 \mathrm{~K}(R=0.118)$. The $\beta$ form was subsequently redetermined at 105 K ( $R=0.041$; Alagar et al., 2005; refcode DLMETA05 in the Cambridge Structual Database, Version 5.35; Allen, 2002). $\alpha$-dl-Met, (I), however, remained one of the few structures of the standard amino acids for which no high-precision experimental data were available (Görbitz, 2015). We here provide a detailed description of this polymorph, obtained from a single-crystal X-ray diffraction investigation at 340 K .

Figure 1
The molecular structure of (I), with $50 \%$ probability displacement ellipsoids and atomic numbering indicated. The L-enantiomer was used as the asymmetric unit, D-enantiomers being generated by symmetry. The minor side-chain orientation [occupancy 0.0491 (18)], with $\mathrm{N} 1-\mathrm{C} 2 B-$ $\mathrm{C} 3 B-\mathrm{C} 4 B$ in a gauche+ rather than a gauche - orientation (Table 1), is shown in a lighter colour.

## 2. Structural commentary

The molecular structure of (I) is shown in Fig. 1. Despite the above-room-temperature conditions, thermal vibrations are comparatively modest. A previously undetected minor conformation with $\chi^{1}(\mathrm{~N} 1-\mathrm{C} 2 B-\mathrm{C} 3 B-\mathrm{C} 4 B)$ in a gauche + orientation (Table 1) has occupancy 0.0491 (18). If the presence of this rotamer is neglected, the refinement converges at $R=0.0586$ rather than 0.0490 . Disorder is extensive for all known phases of DL-Abu and DL-Nva, so it is not unexpected that it is observed here for dL-Met.
The crystal packing of (I) is shown in Fig. 2(a) and may be compared with the structure of $\beta$-dL-Met in Fig. 2(b) (Alagar et al., 2005). The difference between the two forms is not limited to the obvious conformational change for the C3$\mathrm{C} 4-\mathrm{S}-\mathrm{C} 5$ torsion angle, which is trans for the $\beta$ form, but involves a large shift along the $9.8 \AA$ axis and also the characteristic translation half a unit-cell length along the $4.7 \AA$ axis. Notably, hydrogen bonding is virtually unaffected by these displacements. Compared to the 105 K data, $\mathrm{N} 1 \cdots \mathrm{O} 2$ distances in Table 1 are $0.03 \AA$ longer, while $\mathrm{N} 1 \cdots \mathrm{O} 1$ is $0.01 \AA$ shorter. All $\mathrm{H} \cdots A$ distances surprisingly appear to get shorter at 340 K , but this is an artefact resulting from different ways of

Table 1

(a)

Figure 2
(a) The crystal packing of (I), viewed along the monoclinic $b$ axis (top) and the $c$ axis (bottom). The minor side-chain conformation is not shown, and H atoms bonded to C have been omitted for clarity. L-Met and D-Met molecules are shown with light- and dark-grey $C$ atoms, respectively. The blue arrows show the directions of $\mathrm{C} 2-\mathrm{N}$ bond vectors within each of the two sheets constituting a hydrogen-bonded layer. (b) Corresponding views for $\beta$-DL-Met at 105 K (Alagar et al., 2005).
handling the amino group (Görbitz, 2014). In the refinement of $\beta$-DL-Met, this group was fixed with idealized geometry and a perfectly staggered orientation, while we find, upon relaxing the positional parameteres for all three H atoms, a $14^{\circ}$ counterclockwise rotation (for the l-enantiomer) that serves to give three shorter and more linear interactions.

## 3. Supramolecular features

Hydrogen-bond geometries are listed in Table 2. The hydrogen-bonding patterns of all compounds discussed here belong to the LD-LD type (Görbitz et al., 2009), normally

Table 2
Hydrogen-bond geometry ( $\mathrm{A},{ }^{\circ}$ ).

| $D-\mathrm{H} \cdots A$ | $D-\mathrm{H}$ | $\mathrm{H} \cdots A$ | $D \cdots A$ | $D-\mathrm{H} \cdots A$ |

Symmetry codes: (i) $x,-y+\frac{1}{2}, z-\frac{1}{2}$; (ii) $x,-y+\frac{3}{2}, z-\frac{1}{2}$; (iii) $-x+1, y-\frac{1}{2},-z+\frac{1}{2}$; (iv) $x, y-1, z$.
observed for racemates and quasiracemates where at least one of the side chains (for the L - or the D-enantiomer) is linear and leucine, with an isobutyl side chain, is not involved (Görbitz et al., 2009). Apart from a weak $\mathrm{C}^{\alpha}-\mathrm{H} \cdots \mathrm{O}$ contact along the $b$ axis, all intermolecular interactions within a single sheet involve amino acids of opposite chirality (Fig. 3); two N$\mathrm{H} \cdots \mathrm{O}$ interactions between amino acids of the same chirality serve to link the adjacent antiparallel sheets that form a double-sheet hydrogen-bonded layer.

## 4. Synthesis and crystallization

From a saturated solution of DL-Met in water (approximately $30 \mathrm{mg} \mathrm{ml}^{-1}$ ) $50 \mu \mathrm{l}$ was pipetted into a $40 \times 8 \mathrm{~mm}$ test tube, which was then sealed with parafilm. A small hole was pricked in the parafilm and the tube placed inside a larger test tube filled with 2 ml of acetonitrile. The system was ultimately capped and left for 5 d at 293 K . Suitable single crystals in the shape of plates formed as the organic solvent diffused into the aqueous solution.

## 5. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 3. $U_{\text {iso }}$ values for $\mathrm{C} n B$ atoms ( $n=3-$

Figure 3
Hydrogen-bonded sheet of (I). Colour coding as in Fig. 2, except that H3 atoms connecting sheets appear in yellow. The side chains are shown as small spheres. A single L-Met molecule of the adjacent sheet is shown in black wireframe representation. $\mathrm{O} 2^{\mathrm{i}}$ is at $\left(x,-y+\frac{1}{2}, z-\frac{1}{2}\right), \mathrm{O} 2^{\mathrm{ii}}$ at $(x$, $\left.-y+\frac{3}{2}, z-\frac{1}{2}\right)$ and $\mathrm{O} 1^{\mathrm{iii}}$ at $\left(-x+1, y-\frac{1}{2},-z+\frac{1}{2}\right)$ (Table 2). The blue arrow has the same meaning as in Fig. 2.

Computer programs: APEX2 and SAINT (Bruker, 2013), SHELXS2013 and SHELXL2013 (Sheldrick, 2008) and Mercury (Macrae et al., 2008).
5) belonging to the minor side-chain conformation with occupancy 0.0491 (18) were fixed at the $U_{\text {eq }}$ values of the corresponding $\mathrm{C} n$ atom of the major conformation, while S1B was constrained to have the same set of anisotropic displacement parameters as S 1 . A similar procedure was undertaken for $\mathrm{C} 2 B$ and C 2 . Coordinates were refined for amino H atoms; other H atoms were positioned with idealized geometry with fixed $\mathrm{C}-\mathrm{H}=0.96$ (methyl), 0.97 (methylene) or $0.98 \AA$ (methine). $U_{\text {iso }}(\mathrm{H})$ values were set at $1.2 U_{\text {eq }}$ of the carrier atom or at $1.5 U_{\text {eq }}$ for methyl and amino groups.

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Disorder, two side chain orientations.
