# Two isostructural carbamates: the o-tolyl N -(pyridin-3-yl)carbamate and 2-bromophenyl N -(pyridin-3-yl)carbamate monohydrates 

Pavle Mocilac and John F. Gallagher*

School of Chemical Sciences, Dublin City University, Dublin 9, Ireland. *Correspondence e-mail: john.gallagher@dcu.ie

The title carbamate monohydrates, $\mathrm{C}_{13} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{O}_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{C}_{12} \mathrm{H}_{9} \mathrm{BrN}_{2} \mathrm{O}_{2} \cdot \mathrm{H}_{2} \mathrm{O}$, form isomorphous crystals that are isostructural in their primary hydrogenbonding modes. In both carbamates, the primary hydrogen bonding and aggregation involves cyclic amide-water-pyridine moieties as ( $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}-$ $\mathrm{H} \cdots \mathrm{N})_{2}$ dimers about inversion centres [as $R_{4}^{4}(14)$ rings], where the participation of strong hydrogen-bonding donors and acceptors is maximized. The remaining water-carbonyl $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}=\mathrm{C}$ interaction extends the aggregation into two-dimensional planar sheets that stack parallel to the (100) plane. The Br derivative does not participate in halogen bonding. A weak intramolecular $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond is observed in each compound.

## 1. Chemical context

Isomorphous crystals and isostructural compounds feature regularly in series of metalloorganic compounds, lanthanide derivatives as well as in halide-containing organics ( $R X$, where $X=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}$, I and often including the methyl group, Me). Given the vast array of data available in the Cambridge Structural Database (CSD; Groom \& Allen, 2014), the relative proportion of isostructural relationships between sets of crystal structures can readily be ascertained. As such, Oswald \& Crichton (2009) have reported on the regularity with which chlorine ( Cl ) and methyl (Me) groups exhibit isostructurality based on analysis of pairs of compounds in the CSD (van de Streek \& Motherwell, 2005), whereby an estimate of $25-30 \%$ of compound pairs are isostructural. In addition, Polito et al. (2008) have rationalized the differences and similarities between ortho-chloro and ortho-methylbenzoic acids, while the ability of bromines (as $\mathrm{Br}-\mathrm{C}$ ) as well as other halogens to form isostructural pairs/series with methyl groups is well documented (Capacci-Daniel et al., 2008).

These researchers have reported an elegant example of an isostructural series of 1,3-bis(meta-dihalophenyl)ureas (with halo $=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}$ ) that form isomorphous crystals in space group $P 2_{1} 2_{1} 2$, (No. 18) and reported with mono- and di-tolyl analogues (Capacci-Daniel et al., 2008). The molecules associate via $(\mathrm{N}-\mathrm{H})_{2} \cdots \mathrm{O}=\mathrm{C}$ interactions into 1 D chains [ $R_{6}^{1}(6)$ motif] and with $\pi-\pi$ stacking interactions and halogen contacts completing the aggregation. One can surmise that isostructural series in organic molecules are possible whereby 1-2 strong hydrogen bonds dominate the interactions and drive molecular association, despite often semi-effective cumulative competition from other interactions, whilst taking into account the effect of atom/group replacement (Groom \& Allen, 2014).

Further examples in coordination chemistry include the halogen-substituted pseudoterpyridine $\mathrm{Zn}^{\mathrm{II}}$ homoleptic
mononuclear complexes that lack strong hydrogen bonding and with the packing relying on a subtle interplay of weaker interactions, where isostructurality is rare amongst the four ( $\mathrm{F} /$ $\mathrm{Cl} / \mathrm{Br} / \mathrm{I}$ ) halogens (Dumitru et al., 2013). Another example is where the metal complexes $\left(\mathrm{Co}^{\mathrm{II}}, \mathrm{Ni}^{\mathrm{II}}, \mathrm{Cu}^{\mathrm{II}}, \mathrm{Zn}^{\mathrm{II}}\right)$ form an isostructural series when coordinated to a tetraarylazadipyromethene ligand (Palma et al., 2009). The interchangeability effects of $\mathrm{C}-\mathrm{H}$ and $\mathrm{C}-\mathrm{F}$ groups in series of isomeric fluorinated benzamides has been noted (Chopra \& Guru Row, 2008; Donnelly et al., 2008) and for $\mathrm{C}-\mathrm{H} / \mathrm{C}-\mathrm{CH}_{3}$ (Mocilac et al., 2010). More recently, Gomes and co-workers have reported four N -(4-halophenyl)-4-oxo- 4 H -chromene-3carboxamides (halo $=\mathrm{F} / \mathrm{Cl} / \mathrm{Br} / \mathrm{I}$ ), where isostructural $(\mathrm{F} / \mathrm{Cl})$ and $(\mathrm{Br} / \mathrm{I})$ pairs are noted though all four compounds have similar supramolecular structures (Gomes et al., 2015).

## 2. Structural commentary

The carbamates synthesised from condensation reactions (shown in the scheme) as their methyl (CmoM) and bromoderivatives ( $\mathbf{C m o B r}$ ) crystallize as isostructural monohydrates. The differences between the unit-cell parameters ( $a, b, c, \beta$ ) are $<1 \%$ for CmoM (I) and CmoBr (II). Both molecules have similar geometric data (bond lengths and angles) apart from the (ortho) $\mathrm{C}-\mathrm{CH}_{3} / \mathrm{Br}$ bond-length differences and some interplanar data. The molecules have three primary torsion angles along the molecular backbone namely benzene $\mathrm{C}-\mathrm{C}-$ $\mathrm{O}-\mathrm{C}, \mathrm{C}-\mathrm{O}-\mathrm{C}-\mathrm{N}$ and $\mathrm{C}-\mathrm{N}-\mathrm{C}-\mathrm{C}_{\text {pyridine }}$ where the molecule can adopt one of several conformations in solution. In (I) and (II), both aromatic rings are twisted from co-planarity with the four-membered OCON non-H carbamate atom backbone. The $\mathbf{C m o M} \mathrm{C}_{6}$ ring is oriented at an angle of $87.83(4)^{\circ}$ to the central carbamate moiety which lies at an angle of $25.79(7)^{\circ}$ to the $\mathrm{C}_{5} \mathrm{~N}$ ring; the corresponding data for CmoBr are 88.60 (11) and 26.67 (18) ${ }^{\circ}$ and highlighting the

similarities in the two molecular structures. For comparison, we have previously reported an isomer grid of nine related methoxycarbamates (CxxOMe) ( $\boldsymbol{x}=$ ortho-/meta-/para-) in order to compare their crystal structures and molecular models (Mocilac \& Gallagher, 2013).

In the CxxOMe series (Mocilac \& Gallagher, 2013), the primary interaction mode for all nine isomers is the amide $\cdots$ pyridine ( as $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ ) and typically aggregating as catemers, dimers or trimers. However, there is no evidence for the familiar $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}=\mathrm{C}$ (amide $\cdots$ amide) type hydrogen bonding (Mocilac \& Gallagher, 2013). This is in comparison to a series of related benzamides/carboxamides containing one strong donor/two strong acceptors where competition arises resulting in the formation of either (i) $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ or (ii) $\mathrm{N}-$ $\mathrm{H} \cdots \mathrm{O}=\mathrm{C}$ hydrogen bonds as the primary strong interaction (Mocilac et al., 2010, 2012). In the title structures of CmoM (Fig. 1) and $\mathbf{C m o B r}$ (Fig. 2), the presence of a water molecule in the asymmetric unit was unexpected (water typically assists in the decomposition of organic carbamates at room temperature) though it can be shown to confer additional stability on the structure by forming compact hydrogen

Figure 2

Figure 3
Part of the crystal structure of (I) with the primary interactions as a hydrogen-bonded moiety of four carbamates surrounding two hydrogenbonded water molecules and with selected labels. The symmetry-related molecules with suffices $*$, \#, \$ are positioned at $(1-x, 2-y,-z),(1-x$, $\left.\frac{1}{2}+y,-\frac{1}{2}-z\right)$ and $\left(x, \frac{3}{2}-y, \frac{1}{2}+z\right)$, respectively.
bonding and contributing to sheet formation. The retention of carbamate crystal structure integrity is observed over time (as measured in months).

## 3. Supramolecular features

The three primary hydrogen bonds in (I) and (II) as $\mathrm{N} 1-$ $\mathrm{H} 1 \cdots \mathrm{O} 1 W, \quad \mathrm{O} 1 W-\mathrm{H} 1 W \cdots \mathrm{O} 1$ and $\mathrm{O} 1 W-\mathrm{H} 2 W \cdots \mathrm{~N} 23$ (Tables 1 and 2) are classed as strong classical hydrogen bonds with donor-acceptor $(D \cdots A)$ distances $<2.95 \AA$ and $D-$ $\mathrm{H} \cdots A$ angles close to linearity at $180^{\circ}$. In Figs. 3-5 the crystal packing and interactions for $\mathbf{C m o M}$ are shown and in general

Figure 4
A packing diagram of the two-dimensional sheets and interlocking $o$-tolyl groups in CmoM (with aromatic $\mathrm{C}_{6} \mathrm{H}$ atoms removed for clarity). Atoms are drawn as spheres of an arbitrary size.

Figure 5
A packing diagram of $\mathbf{C m o M}$ as two-dimensional sheets as viewed orthogonal to the direction shown in Fig. 4. Atoms are drawn as spheres of an arbitrary size with all H atoms included.
are similar for CmoBr. The amide...water...pyridine hydrogen bonds facilitate aggregation of a centrosymmetric ring of hydrogen bonds [as $R_{4}^{4}(14)$ rings] (Fig. 3) which, when combined with the water. $\cdots$ amide carbonyl $(\mathrm{O}=\mathrm{C})$ interaction, generates a compact flattened 2D sheet of hydrogen bonds that lies parallel to the (100) plane (Figs. 4 and 5). The hydrogen bonding intercepts the $a$-axis at 0.33 and 0.67 along the unit-cell axis and the sheet is a unit-cell length (a) in thickness with hydrophobic aromatic rings at the 2D sheet surfaces. The 3D crystal structure arises where 2D sheets stack parallel to the $a$-axis direction.

## 4. Synthesis and crystallisation

Carbamate formation ( $\mathbf{C m o X} ; \boldsymbol{X}=\mathrm{Me}, \mathrm{Br})$ : The simplest method of phenyl- $N$-pyridinyl-carbamate ( $\mathbf{C} \boldsymbol{x} \boldsymbol{x} \boldsymbol{R}$ ) synthesis is a condensation reaction of aminopyridines with commercially available phenylchloroformates in the presence of base $\left(\mathrm{Et}_{3} \mathrm{~N}\right)$ and solvent $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$. This is performed in an analogous fashion to the Schotten-Baumann reaction and can provide relatively pure products in high yields. However, when using 2-aminopyridines, additional double carbamates are formed where both of the $\mathrm{N}-\mathrm{H} \mathrm{H}$ atoms are replaced by formates. In order to minimize double carbamate formation for these derivatives, reactions are usually performed by mixing the reagents without solvent and base at lower temperature, followed by simple recrystallization.

Another viable route into carbamate chemistry is to use an agent that transforms phenols into the required chloroformate; however, a simpler and more straightforward method for carbamate synthesis is the Curtius rearrangement reaction (or Curtius reaction or degradation) involving the rearrangement of an acyl azide to an isocyanate. The acyl azide (in this case pyridinyl azide) can be formed from the carboxylic

Computer programs: CrysAlis PRO (Agilent, 2012), SHELXS97 (Sheldrick, 2008), SHELXL2014 (Sheldrick, 2015) and PLATON (Spek, 2009)
acid by a suitable agent like diphenylphosphoryl azide. The acid can be easily converted to pyridinyl azides using diphenylphosphoryl azide and at higher temperature ( 343 K ) in the presence of base. The pyridinyl azides rearrange into pyridinyl isocyanates and following reaction with a phenol, the required phenyl- $N$-pyridinyl-carbamate ( $\mathbf{C x x} \boldsymbol{R}$ ) is generated.

Reaction procedure: A mixture of isonicotinic acid $(1.2877 \mathrm{~g}, 10.46 \mathrm{mmol}), \mathrm{Et}_{3} \mathrm{~N}(1.46 \mathrm{ml}, 10.46 \mathrm{mmol})$, and diphenylphosphoryl azide ( $2.258 \mathrm{ml}, 10.46 \mathrm{mmol}$ ) was stirred for 1 h in 30 mL of dry acetonitrile at room temperature. The reaction mixture was carefully heated (water bath) to reflux for 1 h , then with 2 -methylphenol or 2-bromophenol ( 10.46 mmol ) added and the resulting solution heated at reflux temperatures for 7 h , gradually cooled and stirred overnight. If a white precipitate formed, it was filtered, washed with acetonitrile and dried (and usually found to be the pure product). The solvent was removed from the reaction mixture under reduced pressure, the residue dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, washed thrice with a solution of $\mathrm{KHCO}_{3}$ and $\mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{pH}=9)$ and twice with brine/ammonium chloride $(\mathrm{pH}=5)$. The organic fraction was removed in vacuo and the compound recrystallized from diethyl ether and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. If necessary, purification was accomplished by column chromatography using silica as the stationary phase and a mixture of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and methanol (8:1) as mobile phase. Both ComM ( $46 \%$ yield, m.p. range $=352-357 \mathrm{~K})$ and $\mathbf{C o m B r}(21 \%$ yield, m.p. range $=$ $359.2-359.9 \mathrm{~K}$ ) compounds were obtained using this method (Mocilac, 2012).

## 5. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 4. The refinement of structures (I) and (II) were performed similarly. H atoms attached to C atoms were treated as riding using the SHELXL2014 (Sheldrick, 2015) defaults at $294(1) \mathrm{K}$ with $\mathrm{C}-\mathrm{H}=0.93 \AA$ (aromatic) and $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$ (aromatic). The methyl $\mathrm{C}-\mathrm{H}=0.96 \AA$ (aliphatic) and $U_{\text {iso }}(\mathrm{H})=1.5 U_{\text {eq }}(\mathrm{C})$. The amino $\mathrm{N}-\mathrm{H}$ and water $\mathrm{O}-\mathrm{H} \mathrm{H}$ atoms were refined with isotropic displacement parameters in both structures (I) and (II). In (I) the methyl group H atoms were refined as disordered over two sets of sites with equal occupancies $60^{\circ}$ apart.

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters ( $\hat{A}^{2}$ )

## Crystal data

$\mathrm{C}_{12} \mathrm{H}_{9} \mathrm{BrN}_{2} \mathrm{O}_{2} \cdot \mathrm{H}_{2} \mathrm{O}$
$M_{r}=311.14$
Monoclinic, $P 2{ }_{1} / c$
$a=10.9036$ (4) $\AA$
$b=13.0518(3) \AA$
$c=8.9804$ (3) $\AA$
$\beta=96.460(3)^{\circ}$
$V=1269.90(7) \AA^{3}$
$Z=4$
$F(000)=624$

## Data collection

Agilent Xcalibur Sapphire3 Gemini Ultra diffractometer
Radiation source: Enhance (Mo) X-ray Source $\omega$ scans
Absorption correction: analytical
(ABSFAC; Clark and Reid, 1998)
$T_{\min }=0.398, T_{\max }=0.844$
9904 measured reflections
2811 independent reflections
$D_{\mathrm{x}}=1.627 \mathrm{Mg} \mathrm{m}^{-3}$
Melting point: 359.5 K
Mo $K \alpha$ radiation, $\lambda=0.71073 \AA$
Cell parameters from 3330 reflections
$\theta=2.3-27.8^{\circ}$
$\mu=3.24 \mathrm{~mm}^{-1}$
$T=294 \mathrm{~K}$
Plate, colourless
$0.35 \times 0.20 \times 0.04 \mathrm{~mm}$

1881 reflections with $I>2 \sigma(I)$
$R_{\text {int }}=0.029$
$\theta_{\text {max }}=27.9^{\circ}, \theta_{\text {min }}=2.4^{\circ}$
$h=-13 \rightarrow 11$
$k=-16 \rightarrow 16$
$l=-8 \rightarrow 11$
3330 standard reflections every 60 min intensity decay: $1 \%$

## Refinement

Refinement on $F^{2}$
Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.046$
$w R\left(F^{2}\right)=0.106$
$S=1.03$
2811 reflections
175 parameters
0 restraints
Primary atom site location: structure-invariant direct methods

Secondary atom site location: inferred from neighbouring sites
Hydrogen site location: mixed
H atoms treated by a mixture of independent and constrained refinement
$w=1 /\left[\sigma^{2}\left(F_{\mathrm{o}}{ }^{2}\right)+(0.0324 P)^{2}+1.3864 P\right]$
where $P=\left(F_{0}^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3$
$(\Delta / \sigma)_{\max }<0.001$
$\Delta \rho_{\text {max }}=0.68$ e $\AA^{-3}$
$\Delta \rho_{\min }=-0.64 \mathrm{e} \AA^{-3}$

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two 1.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
