The reaction between 5-nitroisatin and phenylhydrazine in acidic ethanol yields the title compound, $C_{14}H_{10}N_4O_3$, whose molecular structure deviates slightly from a planar geometry (r.m.s. deviation = 0.065 Å for the mean plane through all non-H atoms). An intramolecular $N-H\cdots O$ hydrogen bond is present, forming a ring of graph-set motif S(6). In the crystal, molecules are linked by $N-H\cdots O$ and $C-H\cdots O$ hydrogen-bonding interactions into a two-dimensional network along (120), and rings of graph-set motif $R_2^2(8)$, $R_2^2(26)$ and $R_4^4(32)$ are observed. Additionally, a Hirshfeld surface analysis suggests that the molecules are stacked along [100] through $C=O\cdots Cg$ interactions and indicates that the most important contributions for the crystal structure are $O\cdots H$ (28.5%) and $H\cdots H$ (26.7%) interactions. An *in silico* evaluation of the title compound with the DHFR enzyme (dihydrofolate reductase) was performed. The isatin-hydrazone derivative and the active site of the selected enzyme show $N-H\cdots O(ASP29)$, $N-H\cdots O(ILE96)$ and $C_g\cdots Cg(PHE33)$ interactions.

1. Chemical context

The first reports on isatin and the synthesis of isatin derivatives were published independently in Germany and France over 170 years ago (Erdmann, 1841a,b; Laurent, 1841). After the 19th Century, isatin chemistry changed rapidly into a major group of compounds with a wide range of applications in different scientific disciplines, with special attention to medicinal chemistry. For example, the synthesis, in silico evaluation and in vitro inhibition of Chikungunya virus replication by an isatin-thiosemicarbazone derivative was performed recently (Mishra et al., 2016). Other isatin derivatives synthesized in the 1950s (Campaigne & Archer, 1952) had their pharmacological properties in vitro successfully tested against Cruzain, Falcipain-2 and Rhodesian in the 2000s (Chiyanzu et al., 2003), and the crystal structure of one of the derivatives was determined by X-ray diffraction in the 2010s (Pederzolli et al., 2011). The crystal structure determination of isatin-based molecules is an intensive research field, especially in medicinal chemistry. As part of our studies in this area, we now describe the synthesis and structure of the title compound, (I).

2. Structural commentary

For the title compound, the molecular structure matches the asymmetric unit and one intramolecular $N4-H5\cdots O1$ inter-

action of graph-set S(6) is observed (Fig. 1). The molecule is nearly planar with an r.m.s. deviation from the mean plane of the non-H atoms of 0.065 Å and a maximum deviation of 0.1907 (9) Å for atom O2 of the nitro group. The dihedral angle between the indole unit and the phenyl ring is 0.9 (4)°. The plane through the nitro group is rotated by 6.21 (6)° with respect to the indole ring.

3. Supramolecular features

In the crystal, the molecules are connected by centrosymmetric pairs of N1-H1···O1ⁱ interactions (Table 1) into dimers with graph-set motif $R_2^2(8)$. In addition, C10-H6···O3ⁱⁱ and C12-H8···O2ⁱⁱⁱ interactions complete a two-dimensional hydrogen-bonded network with rings of graph-set motif $R_2^2(26)$ and $R_4^4(32)$ (Fig. 2, Table 1). As suggested by Hirshfeld surface analysis, the dimensionality of the structure increases to three-dimensional through the C=O···Cg interactions [C1···Cg = 3.5427 (7) Å, O1···Cg = 3.2004 (7) Å; Cg is the centroid of the C9-C14 ring], building a chain along [100] (Fig. 3). The separation between the C1 and C14 atoms

Table 1 Hydrogen-bond geometry (Å, °).

$D - H \cdot \cdot \cdot A$	D-H	$H \cdot \cdot \cdot A$	$D \cdots A$	$D - H \cdot \cdot \cdot A$
	0.00	2.02	2 7 4 7 0 (1 0)	127
$N4 - H5 \cdots O1$ $N1 - H1 \cdots O1^{i}$	0.88	2.03 1.96	2.8310 (10)	137 171
$C10-H6\cdots O3^{ii}$	0.95	2.63	3.5542 (13)	166
$C12-H8\cdots O2^{m}$	0.95	2.47	3.3943 (13)	163

Symmetry codes: (i) -x + 2, -y, -z + 1; (ii) x, y, z + 1; (iii) -x, -y + 1, -z + 1.

of adjacent molecules in the chain is 3.1744 (11) Å, which is shorter than the sum of the van der Waals radii for carbon atoms (Bondi, 1964; Rowland & Taylor, 1996).

4. Hirshfeld surface analysis

The Hirshfeld surface analysis of the crystal structure indicates that the contribution of O···H intermolecular interactions to the crystal packing amounts to 28.5% and the H...H interactions amount to 26.7%. Other important intermolecular contacts for the cohesion of the structure are (in %): $H \cdot \cdot \cdot C =$ 17.7, $H \cdots N = 8.9$, $C \cdots O = 8.2$, $C \cdots C = 5.5$ and $C \cdots N = 3.3$. The Hirshfeld surface graphical representation with transparency and labelled atoms (Figs. 4 and 5) indicates, in magenta, the locations of the strongest intermolecular contacts. The H1, H8, O1 and O2 atoms are the most important for the intermolecular hydrogen bonding, while the C1 and C14 atoms are the most important for $C \cdots C$ interactions. The $O \cdots H$ contribution to the crystal packing is shown as a Hirshfeld surface fingerprint two-dimensional plot with cyan dots (Wolff *et al.*, 2012). The d_e (y axis) and d_i (x axis) values are the closest external and internal distances (in Å) from given points on the Hirshfeld surface (Fig. 6). The magenta colour on graphical representations of the Hirshfeld surface

matches the N1-H1···O1^{*i*}, C10-H6···O3^{*ii*} and C12-H8···O2^{*iii*} interactions described above. In the same way, the C···Cg interactions can be seen more clearly on the C1=O1 and C14 atoms.

5. Molecular docking evaluation

Finally, for a lock-and-key supramolecular analysis, a molecular docking evaluation between the title compound and the

Figure 4

DHFR enzyme (dihydrofolate reductase) was carried out. Initially, the semi-empirical equilibrium energy of the small molecule was obtained using the PM6 Hamiltonian, but the experimental bond lengths were conserved. The calculated parameters were: heat of formation = 149.41 kJ mol⁻¹, gradient normal = 0.763, HOMO = -8.96 eV, LUMO =-1.66 eV and energy gap = 7.30 eV. The target prediction for 5-nitroisatin-3-phenylhydrazone was calculated with the *SwissTargetPrediction* webserver based on the bioisosteric similarity to the isatin entity (Gfeller *et al.*, 2013). As result of this screening, the title compound showed a promising theo-

Figure 6

Hirshfeld surface fingerprint two-dimensional plot for the 5-nitroisatin-3-phenylhydrazone crystal structure showing the O···H contacts in detail (cyan dots). The O···H contribution for the crystal packing amounts to 28.5%, being the most important intermolecular connection. The d_e (y axis) and d_i (x axis) values are the closest external and internal distances [in Å] from given points on the Hirshfeld surface.

retical structure-activity relationship to kinase proteins sites. The Frequency Target Class for kinases amounts to 44%, while the second best result for phosphatases amounts to 13%. The interactions with enzymes are important features for biologically active molecules, e.g. inhibition of tumor cell proliferation, activation of cell apoptosis mechanisms and blocking of bacterial membrane synthesis. Based on a search for a biological target with pharmacological background, the dihydrofolate reductase was selected for the in silico evaluation (Chen, 2015; Dias et al., 2014; Verdonk et al., 2003), biological target code: DHFR (Protein Data Bank ID: 4KM0; Wei et al., 2005). The isatin-hydrazone derivative and the active site of the selected enzyme matches and the structureactivity relationship can be assumed by the following observed intermolecular interactions: N1-H1···O(ASP29) (1.928 Å), $N4-H5\cdots O(ILE96)$ (1.925 Å) and $Cg \cdots Cg(PHE33)$ (3.567 Å) (Fig. 7).

6. Comparison with a related structure

A recently published article (Bittencourt et al., 2016) reports the structure of (3E)-5-nitro-3-(2-phenylhydrazinylidene)-1Hindol-2(3H)-one, which may be compared with that of the title compound. The molecular structure deviates slightly from the ideal planar geometry and the $C \cdots C$ contacts between the planes are observed. The molecules are linked by N-H···O and C-H···Cl interactions into a two-dimensional hydrogenbonded polymer, a quite similar structure to the title compound. The in silico evaluation of 5-chloroisatin-phenylhydrazone, a molecule with similar crystal packing to the title compound, with and the DNA topoisomerase $II\alpha$ enzyme was performed and the global free energy of $-26.59 \text{ kJ mol}^{-1}$ was found. The evaluation agrees with the literature data for molecular docking and cytotoxic activity of hydrazone derivatives against breast cancer cells (Dandawate et al., 2012) and supports research on the structural determination of other isatin-based molecules. The title compound is commercially available, but its structural analysis by X-ray single crystal

diffraction, Hirshfeld surface calculation and molecular docking evaluation are presented in this work for the first time.

7. Synthesis and crystallization

All starting materials are commercially available and were used without further purification. The synthesis of the title compound was adapted from a procedure reported previously (Fonseca *et al.*, 2011). The glacial acetic acid-catalysed reaction of 5-nitroisatin (2.6 mmol) and phenylhydrazine (2.6 mmol) in ethanol (40 mL) was refluxed for 4 h. After cooling and filtering, an irregular solid was isolated. Single crystals suitable for X-ray diffraction were obtained from a DMF/methanol solution (1:1 ν/ν) on slow evaporation of the solvent.

8. Refinement

Table 2

Even a simulate a la taila

Crystal data, data collection and structure refinement details are summarized in Table 2. Hydrogen atoms were located in a difference Fourier map, but were positioned with idealized geometry and refined isotropically using a riding model, with $U_{\rm iso}({\rm H}) = 1.2U_{\rm eq}({\rm C, N})$, and with C-H = 0.95 Å and N-H = 0.88 Å.

Acknowledgements

ABO is an associate researcher in the project 'Dinitrosyl complexes containing thiol and/or thiosemicarbazone: synthesis, characterization and treatment against cancer', founded by FAPESP, Proc. 2015/12098–0, and acknowledges Professor José C. M. Pereira (São Paulo State University, Brazil) for his support in this work. ABO also acknowledges VCG for the invitation to be a visiting professor at the Federal University of Rio Grande, Brazil, where part of this work was developed. JMV and RLF thank the CAPES Foundation for scholarships. RLF thanks the São Paulo State University, Brazil, for the access to the computer facilities to perform the *in silico* evaluation.

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F², conventional R-factors R are based on F, with F set to zero for negative F^2 . The threshold expression of $F^2 > 2$ sigma(F^2) is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on F² are statistically about twice as large as those based on F, and R- factors based on ALL data will be even larger.
