The title compound, $\left[\mathrm{Sn}\left(\mathrm{CH}_{3}\right)_{2}\left(\mathrm{C}_{5} \mathrm{H}_{8} \mathrm{NOS}_{2}\right)_{2}\right]$, has the $\mathrm{Sn}^{\mathrm{IV}}$ atom bound by two methyl groups which lie over the weaker $\mathrm{Sn}-\mathrm{S}$ bonds formed by two asymmetrically chelating dithiocarbamate ligands so that the coordination geometry is skew-trapezoidal bipyramidal. The most prominent feature of the molecular packing are secondary $\mathrm{Sn} \cdots \mathrm{S}$ interactions $[\mathrm{Sn} \cdots \mathrm{S}=3.5654$ (7) Å] that lead to centrosymmetric dimers. These are connected into a threedimensional architecture via methylene-C-H $\cdots \mathrm{S}$ and methyl-C$\mathrm{H} \cdots \mathrm{O}$ (morpholino) interactions. The $\mathrm{Sn} \cdots \mathrm{S}$ interactions are clearly evident in the Hirshfeld surface analysis of the title compound along with a number of other intermolecular contacts.

## 1. Chemical context

Both binary tin and organotin dithiocarbamates, $R_{n} \mathrm{Sn}\left(\mathrm{S}_{2} \mathrm{CN} R R^{\prime}\right)_{m}$ for $n+m=4$, are well known to exhibit potential biological properties, e.g. anti-cancer (Ferreira et al., 2014), anti-fungal (Yu et al., 2014) and anti-microbial (Ferreira et al., 2012), as well to serve as useful molecular precursors for the generation of 'SnS' nanomaterials (Kevin et al., 2015). The structural chemistry of this class of compound has also attracted considerable interest over the years owing to the occurrence of significant structural diversity observed in seemingly closely related compounds (Tiekink, 2008). As a case in point and related to the title compound, $\left[\mathrm{Sn}\left(\mathrm{CH}_{3}\right)_{2}\left(\mathrm{C}_{5} \mathrm{H}_{8} \mathrm{NOS}_{2}\right)_{2}\right]$ (I), reported herein, are the variations in molecular structure observed for the diorganotin bis(dithiocarbamate)s as discussed in the recent literature (Muthalib et al., 2014; Mohamad et al., 2016, 2017). These $R_{2} \mathrm{Sn}\left(\mathrm{S}_{2} \mathrm{CN} R R^{\prime}\right)_{2}$ structures are known to adopt four distinct coordination geometries with the majority being skew-trapezoidal bipyramidal or octahedral, each based on $\mathrm{C}_{2} \mathrm{~S}_{4}$ donor sets. Fewer examples are known for five-coordinate, trigonalbipyramidal species, e.g. $(t-\mathrm{Bu})_{2} \mathrm{Sn}_{\left(\mathrm{S}_{2} \mathrm{CNMe}_{2}\right)_{2}}$ in which one dithiocarbamate ligand is monodentate (Kim et al., 1987), and seven-coordinate, pentagonal-bipyramidal, e.g. $\left[\mathrm{MeOC}(=\mathrm{O}) \mathrm{CH}_{2} \mathrm{CH}_{2}\right]_{2} \mathrm{Sn}\left(\mathrm{S}_{2} \mathrm{CNMe}\right)_{2}$ where the carbonyl-O atom of one Sn-bound organic substituent is also coordinating the tin atom ( Ng et al., 1989). This last example is of interest as
it demonstrates tin may in fact increase its coordination number by additional interactions. When additional interactions of this type occur intermolecularly, they are termed secondary bonding or tetrel bonding as a Group IV element, tin, is involved (Alcock, 1972; Marín-Luna et al., 2016; Tiekink, 2017). Generally, secondary interactions do not occur for $R_{2} \mathrm{Sn}\left(\mathrm{S}_{2} \mathrm{CN} R R^{\prime}\right)_{2}$ structures as the strong chelating ability of the dithiocarbamate ligand reduces the Lewis acidity of the tin atom. However, in (I) such secondary $\mathrm{Sn} \cdots \mathrm{S}$ interactions do in fact occur. In a continuation of work in this area, herein the synthesis and crystal and molecular structures of (I) are described as well as an analysis of the Hirshfeld surface with a particular emphasis on investigating the role of the secondary Sn. . S interaction.

## 2. Structural commentary

The $\mathrm{Sn}^{\mathrm{IV}}$ atom in the title compound (I), Fig. 1, adopts one of the common coordination geometries found for $R_{2} \mathrm{Sn}\left(\mathrm{S}_{2} \mathrm{CN} R R^{\prime}\right)_{2}$ molecules, i.e. skew-trapezoidal bipyramidal rather than octahedral (Tiekink, 2008). This arises as the chelating dithiocarbamate ligands have asymmetric $\mathrm{Sn}-\mathrm{S}$ bond lengths, Table 1. The values of $\Delta(\mathrm{Sn}-\mathrm{S})=\left[d\left(\mathrm{Sn}-\mathrm{S}_{\text {long }}\right)\right.$ $-d\left(\mathrm{Sn}-\mathrm{S}_{\text {short }}\right]$ for the S 1 - and S3-dithiocarbamate ligands are approximately the same at $0.35 \AA$, but the comparable bonds formed by the S3-dithiocarbamate ligand are systematically longer than those formed by the S1-dithiocarbamate ligand by approximately $0.02 \AA$, Table 1 . The asymmetry in the $\mathrm{Sn}-\mathrm{S}$ bond lengths is reflected in the disparity in the associated $\mathrm{C}-$ S bond lengths with the sulfur atom forming the longer $\mathrm{Sn}-\mathrm{S}$ bond being involved in the significantly shorter, by approximately $0.05 \AA, \mathrm{C}-\mathrm{S}$ bond, Table 1 . Consistent with the skewtrapezoidal bipyramidal geometry about the $\mathrm{Sn}^{\mathrm{IV}}$ atom, the Sn-bound methyl substituents are directed over the longer $\mathrm{Sn}-\mathrm{S}$ bonds and define an angle of $148.24(11)^{\circ}$ at the tin atom. The angle subtended at the tin atom by the strongly bound sulfur atoms of $85.878(19)^{\circ}$ is significantly less than

that formed by the weakly bound sulfur atoms, i.e. $143.066(18)^{\circ}$, and is largely responsible for the formation of the skew-trapezoidal plane about the tin atom.

## 3. Supramolecular features

An interesting feature of the molecular packing in (I) is the formation of a supramolecular dimer sustained by $\mathrm{Sn} \cdots \mathrm{S}$ secondary interactions, as shown in Fig. $2 a$, where two long edges of the translationally displaced trapezoidal planes approach each other to form the interactions. Here, $\mathrm{Sn} \cdots \cdot 4^{\mathrm{i}}$ is 3.5654 (7) $\AA$, which is approximately $0.4 \AA$ shorter than the sum of the van der Waals radii of Sn and S of $3.97 \AA$ (Bondi, 1964); symmetry operation (i): $1-x, 1-y, 1-z$. Connections between the dimeric aggregates are of the type methylene-C$\mathrm{H} \cdots \mathrm{S}$ and methyl-C-H $\cdots \mathrm{O}$ (morpholino), Table 2, and these

Figure 2

interactions combine to generate a three-dimensional architecture, Fig. $2 b$.

## 4. Hirshfeld surface analysis

The Hirshfeld surfaces calculated on the structure of (I) also provide insight into the supramolecular association through secondary $\mathrm{Sn} \cdots \mathrm{S}, \mathrm{S} \cdots \mathrm{S}$ and other contacts, and was performed as per recent publications on related organotin dithiocarbamate structures (Mohamad et al., 2017, 2016). The broad, bright-red spots appearing near the Sn and S 4 atoms on the Hirshfeld surfaces mapped over $d_{\text {norm }}$ in Fig. $3 a$ indicate the formation of the supramolecular dimer through secondary $\mathrm{Sn} \cdots \mathrm{S}$ contacts. On the Hirshfeld surface mapped over elec-

| O2 $\cdots \mathrm{H} 5 B$ | 2.70 | $\frac{1}{2}-x,-\frac{1}{2}+y, \frac{1}{2}-z$ |
| C1 $\cdots \mathrm{H} 3 A$ | 2.88 | $2-x, 1-y, 1-z$ |
| C3 $\cdots \mathrm{H} 12 C$ | 2.86 | $2-x, 1-y, 1-z$ |
| H2A $\cdots \mathrm{H} 11 C$ | 2.36 | $\frac{1}{2}+x, \frac{3}{2}-y, \frac{1}{2}+z$ |

trostatic potential in Fig. 4, these interactions are represented by the blue and red regions around these atoms, respectively. The faint-red spot appearing between the above bright-red spots near the S4 atom indicates the short inter-atomic S...S contact, Table 3, between S4 atoms lying on diagonally opposite vertices of a parallelogram formed by symmetryrelated Sn and S 4 atoms, Fig. 5a. The pair of bright-red spots appearing near the methyl-H12C and morpholine-O1 atoms in Fig. $3 b$ represent the respective donor and acceptor atoms of the $\mathrm{C} 12-\mathrm{H} \cdots \mathrm{O} 1$ interaction. The comparatively weaker methylene- $\mathrm{C} 10-\mathrm{H} \cdots \mathrm{S} 1$ interaction is viewed as a pair of faint-red spots near these atoms in Fig. 3b. It is important to note from the immediate environments about a reference molecule within $d_{\text {norm }}$-mapped Hirshfeld surfaces highlighting intermolecular interactions in Fig. 5 that the secondary $\mathrm{Sn} \cdots \mathrm{S}$ and $\mathrm{S} \cdots \mathrm{S}$ contacts are on one side of the Hirshfeld surface while the atoms participating in $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ interactions are on the other side of the surface.

The overall two-dimensional fingerprint plot, Fig. 6a, and those delineated into $\mathrm{H} \cdots \mathrm{H}, \mathrm{S} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{S}, \mathrm{O} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{O}$, $\mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}, \mathrm{N} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{N}, \mathrm{Sn} \cdots \mathrm{S} / \mathrm{S} \cdots \mathrm{Sn}$ and $\mathrm{S} \cdots \mathrm{S}$ contacts (McKinnon et al., 2007) are illustrated in Fig. 6b-h, respectively; the relative contributions from the various contacts to the Hirshfeld surfaces are summarized in Table 4.

In the fingerprint plot delineated into $\mathrm{H} \cdots \mathrm{H}$ contacts, Fig. $6 b$, the points forming the single short peak at $d_{\mathrm{e}}+d_{\mathrm{i}}<2.4 \AA$ are indicative of the short inter-atomic $\mathrm{H} \cdots \mathrm{H}$ contact listed in Table 3. The involvement of S 1 in the $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ interaction

Figure 4
A view of Hirshfeld surface for (I) mapped over the calculated electrostatic potential in the range -0.053 to +0.078 au. The red and blue regions represent negative and positive electrostatic potentials, respectively.

Table 4
Percentage contributions of inter-atomic contacts to the Hirshfeld surfaces for (I).

| Contact | percentage contribution |
| :--- | :--- |
| $\mathrm{H} \cdots \mathrm{H}$ | 56.8 |
| $\mathrm{~S} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{S}$ | 27.2 |
| $\mathrm{O} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{O}$ | 9.9 |
| $\mathrm{C} \cdots / \mathrm{H} \cdots \mathrm{C}$ | 4.0 |
| $\mathrm{~N} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{N}$ | 1.1 |
| $\mathrm{Sn} \cdots \mathrm{S} / \mathrm{S} \cdots \mathrm{Sn}$ | 0.5 |
| $\mathrm{~S} \cdots \mathrm{~S}$ | 0.5 |

and other sulfur atoms in short inter-atomic $\mathrm{S} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{S}$ contacts, Table 3, results in an overall $27.2 \%$ contribution to the Hirshfeld surface. In the fingerprint plot delineated into $\mathrm{S} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{S}$ contacts, Fig. $6 c$, they appear as overlapping

Figure 5

 $\mathrm{CDCl}_{3}$ di-solvate per binuclear entity; $(f)$ two molecules in the asymmetric unit with each being located about a centre of inversion.
a pair of thin line segments, Fig. $6 f$, and a triangle, Fig. $6 g$, respectively, having minimum $d_{\mathrm{e}}+d_{\mathrm{i}}$ distances at around $3.5 \AA$ and $3.6 \AA$, respectively. The $1.1 \%$ contribution from $\mathrm{N} \cdots \mathrm{H} /$ $H \cdots N$ contacts, Fig. $6 h$, to the Hirshfeld surface reflects an insignificant influence upon the molecular packing as the interatomic separations are greater than the sum of the respective van der Waals radii.

## 5. Database survey

The Cambridge Crystallographic Database (Groom et al., 2016) contains over 110 molecules of the general formula $R_{2} \mathrm{Sn}\left(\mathrm{S}_{2} \mathrm{CN} R R^{\prime}\right)_{2}$. Of these, 12 feature secondary $\mathrm{Sn} \cdots \mathrm{S}$ interactions which, with (I), means approximately $10 \%$ of all $R_{2} \mathrm{Sn}\left(\mathrm{S}_{2} \mathrm{CN} R R^{\prime}\right)_{2}$ structures have $\mathrm{Sn} \cdots \mathrm{S}$ secondary interactions. Selected geometric details for the 13 structures are collated in Table 5. The $\mathrm{Sn} \cdots \mathrm{S}$ interactions assemble molecules in their crystals into three distinct structural motifs. The common motif, $A$, is a dimeric aggregate disposed about a centre of inversion, as is in (I), and is found in the majority of crystals, i.e. nine. This motif is illustrated in Fig. $7 a$ for $\left(\mathrm{PhCH}_{2}\right)_{2} \mathrm{Sn}\left(\mathrm{S}_{2} \mathrm{CNEt}_{2}\right)_{2}$ (Yin et al., 2003). A second zerodimensional motif, $B$, is also known and is readily related to $A$. In the structure of $\mathrm{Me}_{2} \mathrm{Sn}\left(\mathrm{S}_{2} \mathrm{CN}(\mathrm{Et}) \mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{~N}-4\right)_{2}$ (Barba et al., 2012), two independent molecules comprise the asymmetric unit. One of these self-assembles about a centre of inversion as for motif $A$. The nitrogen atom of each pendent 4pyridyl group of the dimeric aggregate thus assembled interacts with the tin atom of the second independent molecule via a $\mathrm{Sn} \cdots \mathrm{N}$ interaction to form the four-molecule aggregate shown in Fig. 7b. The final three molecules are binuclear owing to the presence of bis(dithiocarbamate) ligands and self-assemble into supramolecular chains. In $\left\{\mathrm{Me}_{2} \mathrm{SnS}_{2} \mathrm{CN}\right.$ $\left.\left(\mathrm{CH}_{2} \mathrm{Ph}\right) \mathrm{CH}_{2}\left(1,3-\mathrm{C}_{6} \mathrm{H}_{3}\right) \mathrm{CH}_{2}\left(\mathrm{PhCH}_{2}\right) \mathrm{NCS}_{2} \mathrm{SnMe}_{2}\right\}_{2}$ (Santa-cruz-Juárez et al., 2008), the molecule is situated about a centre of inversion and each tin atom forms an $\mathrm{Sn} \cdots \mathrm{S}$ contact to generate a linear, supramolecular chain, motif $C$, Fig. 7c. A
variation is seen in the crystal of $\mathrm{Me}_{2} \mathrm{SnS}_{2} \mathrm{CN}\left(\mathrm{CH}_{2} \mathrm{CH}_{2}-i\right.$ $\left.\mathrm{Pr}) \mathrm{CH}_{2}\left(1,3-\mathrm{C}_{6} \mathrm{H}_{3}\right) \mathrm{CH}_{2}\left(\mathrm{PhCH}_{2}\right) \mathrm{NCS}_{2} \mathrm{SnMe}_{2}\right\}_{2}$, where there are two independent, centrosymmetric molecules in the asymmetric unit. Here, the resulting supramolecular chain is twisted (Santacruz-Juárez et al., 2008) and is assigned as motif $C^{\prime}$.

The common feature of all motifs listed in Table 5 is that it is one of the weakly bound sulfur atoms that forms the

(c)

Figure 7
Supramolecular aggregation sustained by secondary $\mathrm{Sn} \cdots \mathrm{S}$ interactions (black dashed lines) leading to (a) dimeric aggregates in $\left(\mathrm{PhCH}_{2}\right)_{2} \mathrm{Sn}\left(\mathrm{S}_{2} \mathrm{CNEt}_{2}\right)_{2}$, (b) four-molecule aggregates in $\mathrm{Me}_{2} \mathrm{Sn}\left(\mathrm{S}_{2} \mathrm{C}\right.$ $\left.\mathrm{N}(\mathrm{Et}) \mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{~N}-4\right)_{2}$ and (c) linear supramolecular chain in $\left\{\mathrm{Me}_{2} \mathrm{SnS}_{2} \mathrm{CN}\left(\mathrm{CH}_{2} \mathrm{Ph}\right) \mathrm{CH}_{2}\left(1,3-\mathrm{C}_{6} \mathrm{H}_{3}\right) \mathrm{CH}_{2}\left(\mathrm{PhCH}_{2}\right) \mathrm{NCS}_{2} \mathrm{SnMe}_{2}\right\}_{2}$.
secondary $\mathrm{Sn} \cdots \mathrm{S}$ interaction. Further, the tin-bound groups are relatively sterically unencumbered, allowing for the close approach of sulfur donors to the tin atoms. There are no geometric correlations. However, reflecting the weak nature of these interactions, the sulfur atom forming the $\mathrm{Sn} \cdots \mathrm{S}$ contact does not necessarily form the weaker of the $\mathrm{Sn}-\mathrm{S}_{\text {long }}$ interactions in each molecule. The range of $\mathrm{Sn} \cdots \mathrm{S}$ distances spans nearly $0.5 \AA$ but, again, no correlations between these distances and the $\mathrm{S}_{\text {long }}-\mathrm{Sn}-\mathrm{S}_{\text {long }}$ angles is apparent, i.e. it might be expected that the shorter $\mathrm{Sn} \cdots \mathrm{S}$ interactions would result in wider $\mathrm{S}_{\text {long }}-\mathrm{Sn}-\mathrm{S}_{\text {long }}$ angles.

## 6. Synthesis and crystallization

All chemicals and solvents were used as purchased without purification, and all reactions were carried out under ambient conditions. The melting point was determined using an Electrothermal digital melting point apparatus and was uncorrected. The IR spectrum for (I) was obtained on a Perkin Elmer Spectrum 400 FT Mid-IR/Far-IR spectrophotometer in the range 4000 to $400 \mathrm{~cm}^{-1}$. The ${ }^{1} \mathrm{H}$ NMR spectrum was recorded at room temperature in $\mathrm{CDCl}_{3}$ solution on a Jeol ECA 400 MHz FT-NMR spectrometer.

Sodium morpholinedithiocarbamate (prepared from the reaction between carbon disulfide and morpholine (Merck) in the presence of sodium hydroxide; $1.0 \mathrm{mmol}, 0.185 \mathrm{~g}$ ) in methanol ( 20 ml ) was added to dimethyltin dichloride (Merck, $1.0 \mathrm{mmol}, 0.219 \mathrm{~g})$ in methanol $(10 \mathrm{ml})$. The resulting mixture was stirred and refluxed for 2 h . The filtrate was evaporated until an off-white precipitate was obtained. The precipitate was recrystallized from methanol solution by slow evaporation to yield colourless prisms. Yield: $0.305 \mathrm{~g}, 64.4 \%$; m.p.: 448 K . IR $\left(\mathrm{cm}^{-1}\right): 1465(s), 1423(s) v(\mathrm{C}-\mathrm{N}), 1222(s) v(\mathrm{C}-\mathrm{O})$, $1110(m), 994(s) \nu(\mathrm{C}-\mathrm{S}), 541(m) \nu(\mathrm{Sn}-\mathrm{C}) \mathrm{cm}^{-1} .{ }^{1} \mathrm{H} \mathrm{NMR}$ $\left(\mathrm{CDCl}_{3}\right): 4.18\left(s, 8 \mathrm{H}, \mathrm{CH}_{2} \mathrm{O}\right), 3.77\left(s, 8 \mathrm{H}, \mathrm{NCH}_{2}\right), 1.54(s, 6 \mathrm{H},-$ $\mathrm{CH}_{3}$ ).

## 7. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 6. Carbon-bound H atoms were placed in calculated positions $(\mathrm{C}-\mathrm{H}=0.98-0.99 \AA$ ) and were included in the refinement in the riding-model approximation, with $U_{\text {iso }}(\mathrm{H})$ set to $1.2-1.5 U_{\text {eq }}(\mathrm{C})$. Owing to poor agreement, one reflection, i.e. ( $\overline{12} 15$ ), was omitted from the final cycles of refinement.

## Acknowledgements

## Special details

Geometry. All esds (except the esd in the dihedral angle between two 1.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
