Crystal structure and photoreactive behaviour of *N,N*-diisopropyl(*p*-phenylphenyl)glyoxylamide

Hisakazu Miyamoto^{a*} and Hiroki Takahashi^b^aDepartment of Liberal Arts (Sciences & Mathematics), National Institute of Technology, Kurume College, Fukuoka 830-8555, Japan, and ^bGraduate School of Human and Environmental Studies, Kyoto University, Kyoto 606-8501, Japan.

*Correspondence e-mail: h-miya@kurume-nct.ac.jp

The title compound [systematic name: 2-([1,1'-biphenyl]-4-yl)-2-oxo-*N,N*-bis-(propan-2-yl)acetamide], C₂₀H₂₃NO₂ was synthesized and its photoreactive properties in the crystalline state and in acetonitrile solution were investigated. The compound crystallizes in the chiral space group P₂1₂1₂1. The crystal does not react under UV light irradiation, perhaps due to the presence of the biphenyl group. However, the compound is photoreactive in acetonitrile solution to give racemic 3-(*p*-phenylphenyl)-3-hydroxy-*N*-isopropyl-4,4-dimethylazetidin-2-one.

1. Chemical context

The solid-state photochemistry of *N,N*-dialkyl- α -oxoamides has been studied in relation to penicillin chemistry (Aoyama *et al.*, 1979). The amides undergo Norrish type II cyclization giving β -lactams (Aoyama *et al.*, 1978). The achiral molecule *N,N*-diisopropylphenylglyoxylamide **1a** crystallizes in the chiral space group P₂1₂1₂1 and is transformed to the optically active β -lactam derivative **2a** upon UV light irradiation (Fig. 1; Toda *et al.*, 1987; Sekine *et al.*, 1989). *N,N*-Diisopropyl(*m*-chloro or *m*-methyl or *o*-methylphenyl)glyoxylamides **1b** and **1c** also form chiral crystals, and photoirradiation in the solid state gives optically active β -lactam derivatives **2b** and **2c**, respectively (Toda & Miyamoto, 1993; Hashizume *et al.*, 1995, 1996, 1998). However, *N,N*-diisopropyl(*p*-chloro or *o*-chloro or *p*-methylphenyl)glyoxylamide **1b** and **1c** do not form chiral crystals, and their photoirradiation in the solid state gives racemic β -lactam derivatives **2b** and **2c**, respectively. Therefore, we synthesized the novel title compound **1d** having a phenyl group and investigated whether optically active β -lactam derivative **2d** could be obtained by photoreaction. It was found that **1d** formed a chiral crystal in the chiral space group P₂1₂1₂1, but photoreaction did not proceed in the solid

state. However, photoreaction of **1d** in acetonitrile solution proceeded to give racemic 3-(*p*-phenylphenyl)-3-hydroxy-*N*-isopropyl-4,4-dimethylazetidin-2-one **2d** in 26% yield. In this study, although **1d** formed a chiral crystal, the reason why the photoreaction product of **1d** in the solid state was not obtained was clarified by single-crystal X-ray structural analysis, UV spectroscopy and time-dependent density functional theory (TDDFT) calculations.

2. Structural commentary

Table 1 summarizes intra and intermolecular hydrogen bonds observed in the title compound. The phenyl rings in the biphenyl group are coplanar with the carbonyl group (C7=O1). The torsion angles C2—C1—C7—O1 and C3—C4—C15—C16 are 7.8 (3) and -0.4 (2) $^\circ$, respectively, and the torsion angles O1—C7—C8—O2 and C7—C8—N1—C9 are 97.1 (2) and -3.9 (2) $^\circ$, respectively (Fig. 2). The corresponding torsion angles in **1a** are 88.0 (4) and -5.1 (4) $^\circ$. In order for the Norrish–Yang reaction to take place, the reacting atoms in the molecular structure must be in close proximity. The Yang cyclization of α -oxoamides to β -lactams starts with abstraction of the γ -hydrogen (with respect to the benzylic carbonyl) by the benzylic carbonyl oxygen in the excited state. In the title compound, there are two γ -hydrogen atoms (H5 on C9 and H12 on C12). The distances between the carbonyl oxygen atom O1 and the respective γ -hydrogen atoms H5 and

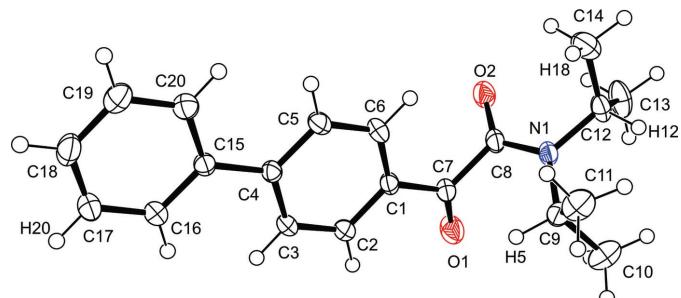

Figure 2

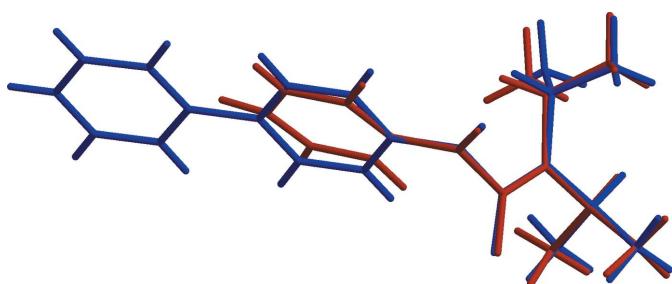

Figure 3
Overlay of molecules **1a** (in red) and **1d** (in blue).

H12 are 2.65 and 5.01 \AA . The former interatomic distance is within the ideal value of up to about 2.7 \AA , at which photoreaction can proceed in the crystal (Konieczny *et al.*, 2018). Moreover, the distance between the reacting C7 and C9 carbon atoms is 2.840 (2) \AA , which is in the range of ideal values of up to about 3.2 \AA . The corresponding distances are 2.78 (4) and 2.871 (4) \AA in **1a**. As shown in Fig. 3, the geometries of the oxoamide moiety of **1d** and **1a** are almost the same. Despite satisfying the geometry and distance requirements for the photoreaction, the corresponding β -lactam was not detected in the solid-state reaction. From the UV spectrum of **1d**, it is considered that the biphenyl group of **1d** absorbs ultraviolet light preventing the solid-state reaction (Fig. 4). In other words, the photocyclization reaction does not proceed in the solid state for at least 300 h because the irradiated UV light is absorbed by the $\pi-\pi^*$ transition of the biphenyl group.

3. DFT calculations

The *GAUSSIAN16* program (Frisch *et al.*, 2016) was used for density functional theory (DFT) calculations. Initial geom-

UV spectra of **1a** (in red, $51.3 \times 10^{-6} M$ MeOH solution) and **1d** (in blue, $48.6 \times 10^{-6} M$ MeOH solution).

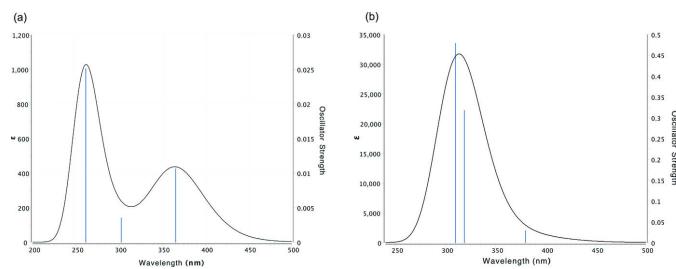

Figure 5
Calculated UV-vis spectra of (a) **1a** and (b) **1d**.

tries of **1a** and **1d** were obtained from XRD data. Hydrogen atoms were optimized at the B3LYP/6-311G(d,p) level (Becke, 1993). The UV-vis spectra of **1a** and **1d** were calculated by the time-dependent density functional theory [TDDFT, B3LYP/6-311G(d,p)] method. In the calculated UV-vis spectra, there were two weak peaks at 254 and 362 nm for **1a**, and there was an intense and broad peak at 310 nm for **1d**. The calculated spectra were similar to the experimental spectra (Fig. 5). For **1a**, the peak at 254 nm corresponds to the $\pi-\pi^*$ transition of the Ph group, while that at the longer wavelength of 362 nm is due to $n-\pi^*$ transitions of the carbonyl groups. For **1d**, the adsorption peak at 376 nm was assigned to $n-\pi^*$ transitions of carbonyl groups. A very weak absorption peak was observed around 370 nm in the experimental spectrum. A mercury lamp has an intense emission at 365 nm, such that the photoreaction for **1a** proceeds rapidly in the solid state. In contrast, the large and broad absorption prevents the solid-state photoreaction for **1d**. Since the molecules can move freely in solution, light irradiation for 60 h was uniformly performed, and it seemed that the reaction proceeded slightly. It has been reported that an oxoamide derivative having a naphthyl group slows down the photoreaction (Natarajan *et al.*, 2005). The relationship between photoreactivity and irradiation wavelength is under investigation.

4. Supramolecular features

In the crystal, the molecules are linked by weak intermolecular C—H \cdots O ($C14-H18\cdots O1$, 2.71 Å) interactions forming a 1D chain structure along the *a*-axis direction (Fig. 6*a*), and C—H \cdots O ($C17-H20\cdots O2$, 2.66 Å) interactions forming a 1D zigzag chain structure along the *b*-axis direction (Fig. 6*b*). Details of these interactions are given in Table 1.

5. Database survey

A search of the Cambridge Structural Database (Version 5.41, last update August 2020; Groom *et al.*, 2016) yielded 18 hits for compounds based on the *N,N*-diisopropylphenylglyoxylamide fragment shown in Fig. 1: no substituent on the phenyl ring (JAGLAE; Sekine *et al.*, 1989), various chiral amido groups on the phenyl ring (KAHWIA, NAHZIG, NAHZUS, NAJBAC,

NAJBEG, NAJBIK, NAJBOQ, NAJBUW, NAJCAD, and NAJCEH; Natarajan *et al.*, 2005), methyl or dimethyl group(s) on the phenyl ring (WIQKUC, YOWVUB, YOWVUF, and YOWWAI; Hashizume *et al.*, 1995), and a chlorine atom on the phenyl ring (ZOHNIT, ZOHNOZ, and ZOHNUF; Hashizume *et al.*, 1996).

6. Synthesis and crystallization

The title compound was prepared according to a reported method (Toda *et al.*, 1987; Sekine *et al.*, 1989), *i.e.*, chlorination of 2-oxo-2-(4-phenylphenyl)acetic acid with thionyl chloride followed by reaction with *N,N*-diisopropylamine. Thus, to an ice-cooled solution of *N,N*-diisopropylamine (16 mL, 0.11 mol) in dry diethyl ether (45 mL) was added a solution of 4-phenylbenzoylformyl chloride (13.8 g, 0.0564 mol) in dry diethyl ether (45 mL), and the reaction mixture was stirred for 10 h at room temperature. After filtration of *N,N*-diisopropylammonium chloride, the filtrate was washed with dilute HCl and aqueous NaHCO₃ and dried over MgSO₄. The crude product was purified by silica gel column chromatography (toluene:ethyl acetate = 9:1) and recrystallized from toluene to give **1d** as colorless prisms (1.02 g, 5.8% yield, m.p. 397–398 K); IR (KBr): ν_{max} 1640, 1680 cm⁻¹; ¹H NMR (500 MHz, CDCl₃): δ 8.01 (*d*, *J* = 8.0 Hz, 2H), 7.73 (*d*, *J* = 8.0 Hz, 2H), 7.63 (*d*, *J* = 8.0 Hz, 2H), 7.50–7.39 (*m*, 3H), 3.75 (*sept*, *J* = 6.9 Hz, 1H), 3.61 (*sept*, *J* = 6.9 Hz, 1H), 1.60 (*d*, *J* = 6.9 Hz, 6H), 1.20 (*d*, *J* = 6.6 Hz, 6H); ¹³C NMR (126 MHz, CDCl₃): δ 190.7, 167.0,

7. Photoreaction

1d (0.100 g, 0.323 mmol) was pulverized in a mortar and irradiated with a 400 W high-pressure mercury lamp for 300 h. No reaction took place, as determined by TLC, IR and NMR spectroscopies. **1d** (0.1368 g, 0.442 mmol) in acetonitrile (10 mL) was irradiated with a 400 W high-pressure mercury lamp for 60 h. The crude product was purified by silica gel column chromatography (toluene:ethyl acetate = 4:1) to give 3-(*p*-phenylphenyl)-3-hydroxy-*N*-isopropyl-4,4-dimethylazetidin-2-one **2d** as a colorless powder (0.035 g, 26% yield, m.p. 467–469 K); IR (KBr): ν_{max} 3200, 1720 cm^{−1}; ¹H NMR (60 MHz, CDCl₃): δ 7.60–7.00 (*m*, 9H), 4.64 (*s*, 1H), 3.57 (*sept*, *J* = 7.0 Hz, 1H), 1.44 (*d*, *J* = 7.0 Hz, 6H), 1.27 (*s*, 3H), 0.87 (*s*, 3H); ESIMS m/z : calculated for $C_{20}H_{23}NNaO_2 [M + Na]^+$, 322.1621; found, 322.1569.

8. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. All H atoms were positioned in geometrically calculated positions (C—H = 0.95–0.98 Å) and refined using a riding model with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ and 1.5*U_{eq}*(C-methyl). The Flack parameter *x* is 0.1 (4) as shown in Table 2. The standard uncertainty is large. The Flack and Hooft (Hooft *et al.*, 2008) parameters are strongly indicative of the correct absolute configuration, even when the standard uncertainties are large (Thompson & Watkin, 2011). Hooft [0.19 (16)] and Parsons parameters [0.2 (3)] (Parsons *et al.*, 2013) were calculated using PLATON (Spek, 2020).

Acknowledgements

Theoretical calculations were performed at the Super Computer System of Academic Centre for Computing and Media Studies, Kyoto University.

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
