# Cyclopentadienone triisocyanide iron complexes: general synthesis and crystal structures of tris(2,6-dimethylphenyl isocyanide)( $\eta^4$ -tetraphenylcyclopentadienone)iron and tris(naphthalen-2-yl isocyanide)( $\eta^4$ -tetraphenylcyclopentadienone)iron acetone hemisolvate

André Bütikofer and Peter Chen\*

Irradiation of a toluene solution containing cyclopentadienone tricarbonyl iron complexes and isocyanides with blue LEDs afforded the formation and isolation of 12 triisocyanide complexes, two of which, namely tris(2,6-dimethylphenyl isocyanide)( $\eta^4$ -tetraphenylcyclopentadienone)iron,  $[\text{Fe}(\text{C}_9\text{H}_9\text{N})_3(\text{C}_{29}\text{H}_{20}\text{O})]$ , and tris(naphthalen-2-yl isocyanide)( $\eta^4$ -tetraphenylcyclopentadienone)iron acetone hemisolvate,  $[\text{Fe}(\text{C}_{11}\text{H}_7\text{N})_3(\text{C}_{29}\text{H}_{20}\text{O})]_2 \cdot \text{C}_3\text{H}_6\text{O}$ , could be characterized crystallographically. The air-stable compounds were purified by column chromatography and were characterized by  $^1\text{H}$  NMR,  $^{13}\text{C}$  NMR, elemental analysis and HRMS. NMR and XRD data indicate generally more electron-rich  $\text{Fe}^0$  centers compared to the corresponding tricarbonyl compounds.

## 1. Chemical context

While cyclopentadienone tricarbonyl iron complexes are well known species and have been established as pre-catalysts for hydrogenation and transfer hydrogenation reactions among other types and reactions (Quintard & Rodriguez, 2014; Pignataro & Gennari, 2020), the corresponding triisocyanide complexes have thus far not been described in the literature. Considering the electronic similarity between CO and CNR ( $R$  = alkyl or aryl) ligands (Pruchnik & Duraj, 1990), the incorporation of isocyanide ligands into the cyclopentadienone iron complex framework could open up new handles to tune the electronic and steric properties of the compounds by variation of the  $R$  group on the isocyanide ligands.

Inspired by the procedure described for obtaining cyclopentadienone triacetonitrile complexes by irradiation of the corresponding tricarbonyl complexes with light in acetonitrile solution (Knölker *et al.*, 1999), it was found that irradiating a toluene solution (*ca* 0.1  $M$  total concentration) of a cyclopentadienone tricarbonyl complex [1 equiv., cyclopentadienone = tetraphenylcyclopentadienone (TPCPD) or 1,3-bis-(trimethylsilyl)-4,5,6,7-tetrahydro-2*H*-inden-2-one (BTTHI)] and a slight excess of an isocyanide  $\text{RNC}$  [4 equiv.,  $R$  =  $\text{CH}_2\text{Ts}$  ( $\text{Ts}$  = toluenesulfonyl),  $t\text{Bu}$ , Bu, 2,6-DMP (DMP = dimethylphenyl), 2-Naphth (Naphth = Naphthyl),  $\text{CH}_2\text{Ph}$ ] with blue LEDs under a nitrogen atmosphere overnight afforded the corresponding triisocyanide complexes in moderate to good

yields (20–85%) (Fig. 1). For two of the twelve isolated compounds, namely  $\text{Fe}(\text{CN-2,6-DMP})_3\text{-TPCPD}$  and  $\text{Fe}(\text{CN-2-Naphth})_3\text{-TPCPD}$ , single crystals suitable for XRD could be obtained. Their structures are reported herein.

$\text{Fe}(\text{CN-2,6-DMP})_3\text{-TPCPD}$

$\text{Fe}(\text{CN-2-Naphth})_3\text{-TPCPD}\cdot 0.5\text{Me}_2\text{CO}$

The isolated complexes were inactive in hydrogenation and transfer hydrogenation reactions of acetophenone in  $i\text{PrOH}$  (1 mol% catalyst loading, 363 K, 10 bar  $\text{H}_2$ ). Addition of  $\text{Me}_3\text{NO}$ , as is routinely done for activating the corresponding tricarbonyl complexes, did not lead to turnover either. It is assumed that neither  $\text{Me}_3\text{NO}$  nor elevated temperatures are

**Figure 1**  
Synthetic route to access cyclopentadienone triisocyanide complexes starting from the corresponding tricarbonyl complexes by irradiation with blue LEDs.

**Figure 2**

able to cleave one of the  $\text{Fe}-\text{CNR}$  bonds to free up a coordination site needed for catalysis. While potential applications of these complexes in catalysis were unsuccessful, our studies nevertheless prompted us to seek systematic relationships between the ligand properties and either the structural or the functional properties of the complexes.

## 2. Structural commentary

Comparisons to tricarbonyl( $\eta^4$ -tetraphenylcyclopentadienone)iron [ $\text{Fe}(\text{CO})_3\text{-TPCPD}$ ] will be based on the reported structure (Gupta *et al.*, 2000; CCDC deposition number 142285).

**Figure 3**  
Crystal structure of  $\text{Fe}(\text{CN-2-Naphth})_3\text{-TPCPD}$ . Displacement ellipsoids are shown at the 50% probability level. The second complex in the asymmetric unit, hydrogen atoms and the co-crystallized acetone molecule are not shown for clarity.

**Figure 4**  
The two independent  $\text{Fe}(\text{CN-2-Naphth})_3\text{-TPCPD}$  molecules in the asymmetric unit viewed along the Fe–Fe axis. In the crystal, the molecules appear in pairs that are rotated by  $180^\circ$  with respect to each other and show an interlocked arrangement of the naphthyl groups.

$\text{Fe}(\text{CN-2,6-DMP})_3\text{-TPCPD}$  (Fig. 2) crystallizes in the  $Pca_21$  space group and features one complex molecule per asymmetric unit with no co-crystallized solvent molecules. The average Fe–CNR bond distance is 1.84 (1) Å. The average C–Fe–C angle is  $94 (3)^\circ$ .  $\text{Fe}(\text{CN-2-Naphth})_3\text{-TPCPD}$  (Figs. 3 and 4) crystallizes in the  $P2_1$  space group and features two complex molecules and a co-crystallized acetone molecule in the asymmetric unit. The average Fe–CNR distance is 1.831 (6) Å. The average C–Fe–C angle is  $96 (2)^\circ$ . In one of the complex molecules, there is disorder in two of the three naphthyl groups with site-occupancy factors of 0.911 (3) and 0.089 (3).  $\text{Fe}(\text{CN-2,6-DMP})_3\text{-TPCPD}$  shows a C=O double bond length of 1.243 (5) Å, while the two complexes in the crystal structure of  $\text{Fe}(\text{CN-2-Naphth})_3\text{-TPCPD}$  show lengths of 1.247 (4) and 1.243 (4) Å. These values are marginally longer than the C=O double bond in  $\text{Fe}(\text{CO})_3\text{-TPCPD}$ , in which the C=O double bond length is 1.22 (1) Å. Both compounds feature the iron atom in the formal 0 oxidation state. The cyclopentadienone ligand is coordinated in an  $\eta^4$  fashion.

In  $\text{Fe}(\text{CN-2,6-DMP})_3\text{-TPCPD}$ , the average distance between Fe and the diene carbon atoms (C5, C6, C7, C8) is 2.11 (3) Å and the Fe distance to the ketonic carbon atom (C4) is 2.361 (4) Å. In  $\text{Fe}(\text{CN-2-Naphth})_3\text{-TPCPD}$ , the average distance between Fe and the diene carbon atoms (C5, C6, C7, C8) is 2.10 (3) Å and the distances from Fe to the ketonic carbon atom (C4) are 2.367 (3) and 2.373 (3) Å. Compared to values in  $\text{Fe}(\text{CO})_3\text{-TPCPD}$  [2.14 (2) Å and 2.40 (1) Å, respectively], the values measured in the iso-

**Table 1**  
 $^{13}\text{C}$  NMR chemical shifts (in p.p.m.) for the cyclopentadienone ring carbon atoms (C4, C5, C6, C7, C8) (TPCPD / BTTHI).

X	C4	C5/C8	C6/C7
O	170.0 / 181.4	82.7 / 71.9	104.2 / 111.1
NCH <sub>2</sub> Ts	n/a / 178.3	79.5 / 66.7	99.1 / 105.5
N-2-Naphth	165.3 / 178.2	78.5 / 66.6	98.8 / 104.8
N-2,6-DMP	165.9 / n/a	77.4 / 65.7	98.8 / 104.3
NCH <sub>2</sub> Ph	163.6 / n/a	76.0 / 63.9	96.6 / 102.3
NBu	163.3 / n/a	74.8 / 61.6	96.1 / 101.0
N'Bu	161.8 / 175.0	75.1 / 62.2	95.6 / 100.7

All spectra recorded in  $\text{CDCl}_3$ . Spectra were referenced to the solvent signal at 77.16 p.p.m. (Fulmer *et al.*, 2010).  $^{13}\text{C}$  NMR data for  $\text{Fe}(\text{CO})_3\text{-BTTHI}$  were obtained from the literature (Moulin *et al.*, 2013).

cyanide complexes are marginally smaller, *i.e.* the Fe–diene bond is shorter.

The envelope angles, defined as the angle between the plane spanned by C5, C6, C7 and C8 with the plane spanned by C4, C5, C8 and O1, are  $14.1689 (3)^\circ$  for  $\text{Fe}(\text{CN-2,6-DMP})_3\text{-TPCPD}$  and  $15.6550 (2)^\circ$  and  $12.8805 (2)^\circ$  in  $\text{Fe}(\text{CN-2-Naphth})_3\text{-TPCPD}$ . They are lower than the envelope angle for  $\text{Fe}(\text{CO})_3\text{-TPCPD}$ , which is reported to be  $16^\circ$ . The isocyanide complexes show a flatter cyclopentadienone ligand, which, together with the elongated C=O double bonds, could indicate more ‘cyclopentadienyl character’, reflecting the high electron density on iron and its presumed propensity to redistribute its electrons into the ligands.

The C–N–C angles in the isocyanide ligands in  $\text{Fe}(\text{CN-2,6-DMP})_3\text{-TPCPD}$  are  $178.6 (4)$ ,  $163.5 (4)$  and  $159.5 (4)^\circ$ . In  $\text{Fe}(\text{CN-2-Naphth})_3\text{-TPCPD}$ , the angles are  $170.5 (3)$ ,  $168.6 (3)$  and  $168.5 (3)^\circ$  for the complex without disorder and  $175.8 (3)$ ,  $162.6 (3)$  and  $157.9 (12)^\circ$  in the complex with disorder. The bending away from  $180^\circ$  indicates significant back-bonding from the  $\text{Fe}^0$  center into the  $\pi^*_{\text{CN}}$  orbitals of the ligands. For  $\text{Fe}(\text{CN-2,6-DMP})_3\text{-TPCPD}$ , the isocyanide ligand showing an almost linear C–N–C angle of  $178.6 (4)^\circ$ , is located parallel to the C=O double bond of the cyclopentadienone ligand. This could indicate that, in this position in the  $\text{Fe}(\text{CNR})_3$  fragment, only a little back-bonding takes place, and that the  $\text{Fe}^0$  atom prefers to distribute its electron density into the two isocyanide ligands facing away from the C=O double bond. In  $\text{Fe}(\text{CN-2-Naphth})_3\text{-TPCPD}$ , the spread of the angles is generally lower. It can furthermore be observed that the C–N–C bends are angled towards the cyclopentadienone ligand in the same molecule. As the asymmetric unit features two interlocked  $\text{Fe}(\text{CN-2-Naphth})_3\text{-TPCPD}$  molecules (the C–N–C bends face away from the other complex molecule in the pairs), it is proposed that the lower spread and lack of trend as to which position in the  $\text{Fe}(\text{CNR})_3$  fragment experiences how much back-bonding is due to crystal-packing forces. This is not observed in  $\text{Fe}(\text{CN-2,6-DMP})_3\text{-TPCPD}$ , since there is no obvious intermolecular interaction in this case.

$^{13}\text{C}$  NMR analysis revealed similar experimental evidence for the higher electron density on iron. Table 1 shows the  $^{13}\text{C}$  NMR chemical shifts for the ring carbon atoms C4, C5, C6, C7 and C8 in the complexes  $\text{Fe}(\text{CX})_3\text{-TPCPD}$  (X = O, NR). The corresponding values for complexes with the BTTHI

ligand are shifted *ca* 5 ppm downfield for C4 and C6/C7 and *ca* 10 ppm upfield for C5/C8 and follow the same overall trend as the complexes with TPCPD. It can be observed that the signals are all shifted upfield, *i.e.* to lower chemical shifts, compared to the parent tricarbonyl complex. This observation can be explained by considering that isocyanides are weaker  $\pi$ -acceptors and stronger  $\sigma$ -donors compared to CO. They thus render the iron center more electron rich and therefore lead to more electron density and thus shielding in the cyclopentadienone ligand. Complexes with isocyanide ligands bearing electron-withdrawing or aromatic substituents (CH<sub>2</sub>Ts, 2-Naphth, 2,6-DMP) show more deshielded signals compared to isocyanide ligands with electron-donating substituents (CH<sub>2</sub>Ph, Bu, <sup>t</sup>Bu).

Furthermore, <sup>13</sup>C NMR analysis showed that the CNR signals are generally more shielded by 2–5 ppm for complexes bearing the TPCPD ligand compared to the BTTHI ligand, indicative of stronger  $d_{\text{Fe}}$  to  $\pi^*_{\text{CN}}$  back-bonding with BTTHI, since more back-donation generally leads to higher chemical shifts (Pruchnik & Duraj, 1990). TPCPD can thus be said to be a stronger acceptor than BTTHI, rendering the Fe center less electron rich.

### 3. Supramolecular features

In the crystal of **Fe(CN-2-Naphth)<sub>3</sub>-TPCPD**, the complexes form pairs with the Fe(CNR)<sub>3</sub> fragments facing each other. The complexes are rotated by approximately 180° relative to each other. The naphthyl groups form an interlocked structure. No obvious intermolecular interactions are observed in **Fe(CN-2,6-DMP)<sub>3</sub>-TPCPD**.

### 4. Database survey

In a search of the Cambridge Structural Database (WebCSD, accessed May 2023, Groom *et al.*, 2016), three structures featuring an iron triisocyanide moiety with the iron center in the 0 oxidation state were found in which the iron is bound to a diene (Fig. 5). Bassett and co-workers reported the complex tris(*tert*-butylisocyanide)( $\eta^4$ -*N*<sup>1</sup>,*N*<sup>4</sup>-di-*tert*-butyl-2,3-diphenylbuta-1,3-diene-1,4-diimine)iron, which could be accessed by either treating Fe<sub>2</sub>(CN<sup>t</sup>Bu)<sub>9</sub> or Fe(CN<sup>t</sup>Bu)<sub>5</sub> with diphenylacetylene (Bassett *et al.*, 1978, CCDC deposition number 1107207; Bassett *et al.*, 1980, CCDC deposition number 1107208). Sunada and co-workers reported the structure of tris( $\eta^4$ -adamantyl isocyanide)(1,3,5,7-cyclotetraene)iron (Sunada *et al.*, 2015, CCDC deposition number 1416957). The compound was prepared by treating di(1,3,5,7-cyclotetraene)iron with three equivalents of adamantyl isocyanide. The analogous structure with <sup>t</sup>BuNC instead of adamantyl isocyanide was also reported (Bassett *et al.*, 1981), but not crystallographically characterized. Brennessel and Ellis reported the structure of Fe( $\eta^4$ -anthracene)(CN-2,6-DMP)<sub>3</sub> (Brennessel & Ellis, 2022, CCDC deposition number 2127596). The structure features the most similar coordination environment around iron compared to **Fe(CN-2,6-DMP)<sub>3</sub>-TPCPD** and **Fe(CN-2-Naphth)<sub>3</sub>-TPCPD** found in the database. The

**Figure 5**  
Crystallographically characterized Fe<sup>0</sup> triisocyanide diene complexes reported in the CSD.

average C—Fe—C angle is 95 (5)°, which is very similar to the values observed in **Fe(CN-2,6-DMP)<sub>3</sub>-TPCPD** and **Fe(CN-2-Naphth)<sub>3</sub>-TPCPD** [94 (3)° and 96 (2)°, respectively]. The reported envelope angle between the iron coordinating  $\eta^4$ -diene unit and the exo-naphthalene portion is 30.76 (16)° for Fe( $\eta^4$ -anthracene)(CN-2,6-DMP)<sub>3</sub>, which is significantly higher than the angle observed with the carbonyl units in the cyclopentadienone complexes. This could be due to more aromatic character in the cyclopentadienone ligand made possible by the ketone unit. Both tris( $\eta^4$ -adamantylisocyanide)(1,3,5,7-cyclotetraene)iron and Fe( $\eta^4$ -anthracene)(CN-2,6-DMP)<sub>3</sub> show a similar back-bonding situation to **Fe(CN-2,6-DMP)<sub>3</sub>-TPCPD**, namely that the isocyanide ligands on the side of the 2,3 positions of the diene (C6 and C7) show more acute C—N—C angles than the ligand on the side of the 1,4 positions (C5 and C8) [177.6 (3), 174.1 (3) and 166.5 (3)° and 170.8 (2), 162.0 (2) and 138.9 (2)° for Fe( $\eta^4$ -anthracene)(CN-2,6-DMP)<sub>3</sub> and tris( $\eta^4$ -adamantylisocyanide)(1,3,5,7-cyclotetraene)iron, respectively]. Since in these crystals no obvious intermolecular interactions can be observed, as in the case for **Fe(CN-2,6-DMP)<sub>3</sub>-TPCPD**, the differences in angles depending on the position could be rationalized by electronic effects.

### 5. Synthesis and crystallization

The general procedure for the synthesis of the triisocyanide complexes is as follows: Under an atmosphere of N<sub>2</sub>, the iron

tricarbonyl complex (1 equiv.) and the isocyanide (4 equiv.) were dissolved in toluene (*ca* 0.1 M total concentration). Drying or degassing of the solvent was not found to be necessary. The solution was irradiated with blue LEDs (RND Components RND 135-00259, 4.8 W, 470 nm) at room temperature overnight. The next day, the solution was directly loaded onto a silica packed column and purified by column chromatography using the appropriate eluent as indicated below. The relevant, yellow-colored fractions were combined and concentrated under reduced pressure. For complexes bearing the TPCPD ligands with electron-rich isocyanides (CNCH<sub>2</sub>Ph, CN<sup>t</sup>Bu, CNBu), it was necessary to perform rotary evaporation at 298 K instead of 313 K because of the thermal instability of these compounds, as evidenced by the observation of the dark-purple color of the TPCPD ligand during thin layer chromatography (TLC) analysis. The complexes were isolated as yellow to orange solids and were characterized by <sup>1</sup>H NMR, <sup>13</sup>C NMR, elemental analysis and HRMS. Single crystals of the compounds **Fe(CN-2,6-DMP)<sub>3</sub>-TPCPD** and **Fe(CN-2-Naphth)<sub>3</sub>-TPCPD** were obtained by suspending the solids in acetone to obtain a saturated solution, filtering off the solids and storing the saturated solution at 253 K in a freezer.

The decomposition upon heating, presumably due to the loss of the cyclopentadienone ligand, appears to depend on how electron rich the complex is as a whole, as indicated by <sup>13</sup>C NMR, with more electron density on the cyclopentadienone ligand leading to thermal instability. Combining the observations made above, it can be said that more thermally stable complexes can be expected by combining strongly  $\pi$ -accepting isocyanide ligands with weakly electron-accepting cyclopentadienone ligands, reminiscent of a push–pull interaction between the cyclopentadienone ligand and the isocyanide ligands mitigated by the iron center.

**Fe(CO)<sub>3</sub>-BTTHI** and tetraphenylcyclopentadienone were prepared according to literature methods (Moulin *et al.*, 2013; Liang, 2019).

**Tricarbonyl( $\eta^4$ -tetraphenylcyclopentadienone)iron:** A dried and argon-flushed 100 ml two-necked round-bottom flask equipped with a stir bar and a reflux condenser was charged with 2.0 g tetraphenylcyclopentadienone (5.2 mmol, 1 equiv.), 1.88 g Fe<sub>2</sub>(CO)<sub>9</sub> (5.2 mmol, 1 equiv.) and 50 ml dry toluene. The mixture was heated to reflux overnight. The next day, the mixture was allowed to cool to room temperature. The mixture was passed through a pad of silica and eluted first with toluene to remove Fe(CO)<sub>5</sub> and unreacted tetraphenylcyclopentadienone. The eluent was changed to EtOAc and the orange band was collected. The orange solution was concentrated under reduced pressure. The product was obtained as a yellow–orange solid after drying *in vacuo* (2.0 g, 74%). <sup>1</sup>H NMR ( $\delta$ , 400 MHz, CDCl<sub>3</sub>): 7.64–7.54 (*m*, 4H), 7.32–7.23 (*m*, 8H), 7.23–7.14 (*m*, 8H). <sup>13</sup>C NMR ( $\delta$ , 100 MHz, CDCl<sub>3</sub>): 208.7, 170.0, 132.0, 131.0, 130.4, 130.1, 128.9, 128.21, 128.18, 128.0, 104.2, 82.7. ## 6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. H atoms were positioned geometrically (C–H = 0.95–0.98 Å) and refined as riding with  $U_{\text{iso}}(\text{H}) = 1.2\text{--}1.5U_{\text{eq}}(\text{H})$ . The crystal for **Fe(CN-2-Naphth)<sub>3</sub>-TPCPD** was twinned. Two domains, with approximate refined mass fractions of 3:1 and rotated by approximately 179°, were found and integrated simultaneously. The best model in terms of residual densities and their location, *R* values and weighting scheme was obtained using de-twinned HKLF4 data.

## Acknowledgements

X-ray services were provided by SMOCC – The Small Molecule Crystallography Center of ETH Zurich. The authors thank Nils Trapp and Michael Solar for the measurements and determination of the crystal structures shown in this work.

## Funding information

Funding for this research was provided by: NCCR Catalysis (grant No. 180544); ETH Zürich.

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

**Tris(naphthalen-2-yl isocyanide)( $\eta^4$ -tetraphenylcyclopentadienone)iron acetone hemisolvate (twin)**

*Crystal data*

$[\text{Fe}(\text{C}_{11}\text{H}_7\text{N})_3(\text{C}_{29}\text{H}_{20}\text{O})_2]_2 \cdot \text{C}_3\text{H}_6\text{O}$

$M_r = 1857.73$

Monoclinic,  $P2_1$

$a = 15.2471 (1) \text{ \AA}$

$b = 19.8604 (1) \text{ \AA}$

$c = 15.5785 (1) \text{ \AA}$

$\beta = 99.378 (1)^\circ$

$V = 4654.33 (5) \text{ \AA}^3$

$Z = 2$

$F(000) = 1936$

$D_x = 1.326 \text{ Mg m}^{-3}$

Cu  $K\alpha$  radiation,  $\lambda = 1.54184 \text{ \AA}$

Cell parameters from 61660 reflections

$\theta = 2.9\text{--}78.4^\circ$

$\mu = 2.98 \text{ mm}^{-1}$

$T = 100 \text{ K}$

Needle, clear colourless

$0.18 \times 0.07 \times 0.05 \text{ mm}$

*Data collection*

XtaLAB Synergy, Dualflex, Pilatus 300K  
diffractometer

Radiation source: micro-focus sealed X-ray  
tube, PhotonJet (Cu) X-ray Source

Mirror monochromator

Detector resolution:  $5.8140 \text{ pixels mm}^{-1}$

$\omega$  scans

Absorption correction: gaussian  
(CrysAlisPro; Rigaku OD, 2021)

$T_{\min} = 0.779$ ,  $T_{\max} = 1.000$

89473 measured reflections

18788 independent reflections

17761 reflections with  $I > 2\sigma(I)$

$R_{\text{int}} = 0.050$

$\theta_{\max} = 78.8^\circ$ ,  $\theta_{\min} = 2.9^\circ$

$h = -19 \rightarrow 19$

$k = -23 \rightarrow 24$

$l = -19 \rightarrow 19$

*Refinement*

Refinement on  $F^2$

Least-squares matrix: full

$R[F^2 > 2\sigma(F^2)] = 0.036$

$wR(F^2) = 0.100$

$S = 1.07$

18788 reflections

1390 parameters

1606 restraints

Primary atom site location: dual

Hydrogen site location: inferred from  
neighbouring sites

H-atom parameters constrained

$w = 1/[\sigma^2(F_o^2) + (0.0732P)^2 + 0.229P]$

where  $P = (F_o^2 + 2F_c^2)/3$

$(\Delta/\sigma)_{\max} = 0.001$

$\Delta\rho_{\max} = 0.28 \text{ e \AA}^{-3}$

$\Delta\rho_{\min} = -0.37 \text{ e \AA}^{-3}$

Absolute structure: Classical Flack (1983)

method preferred over Parsons because s.u.  
lower

Absolute structure parameter:  $-0.004 (2)$

*Special details*

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

**Refinement.** Twinned specimen. De-twinned HKLF4 gave best results.

*Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters ( $\text{\AA}^2$ )*
