The structure of the title complex,  $[Pb(NO_3)(C_5H_{11}NO_2)_2(H_2O)_2]NO_3$ , had been determined previously at 173 and 193 K, and is now reported at 296 K, in the same space group. The main difference with the low-temperature structures is that a methyl group of one valine ligand is clearly disordered over two positions, for which the occupancies converged to 0.56 (3) and 0.44 (3). Bond-length variations within the coordination sphere of  $Pb^{II}$  as a function of  $T$  are difficult to assess because uncertainties on these parameters are high. On the other hand,  $Pb \cdots O$  distances above 2.9 Å cannot be assigned unambiguously to formal  $Pb-O$  bonds. As a consequence, the polymeric nature of the complex previously described at 173 K is uncertain, as well as the actual coordination number of  $Pb^{II}$ , and it is thus not possible to determine if the metal environment is holo- or hemidirected.

## Chemical scheme

## Structure description

The complex  $[Pb(H_2O)_2(L\text{-valine})_2(NO_3)]^+NO_3^-$  has been synthesized by many groups, in a context related to lead–aminoacids and lead–enzymes interactions studies. The X-ray structure has been published twice, using data collected at  $T = 173$  K (Burford *et al.*, 2004) and  $T = 193$  K (Saunders *et al.*, 2011). However, these structures appear with different names and connectivity diagrams in the CSD: the former, E SAPET, is considered as a polymeric compound with the coordinated nitrate ion bridging metal centers in the crystal, while the latter, E SAPET01, is deposited as a monomeric species. These representations are indeed consistent with the structure descriptions given in both articles.

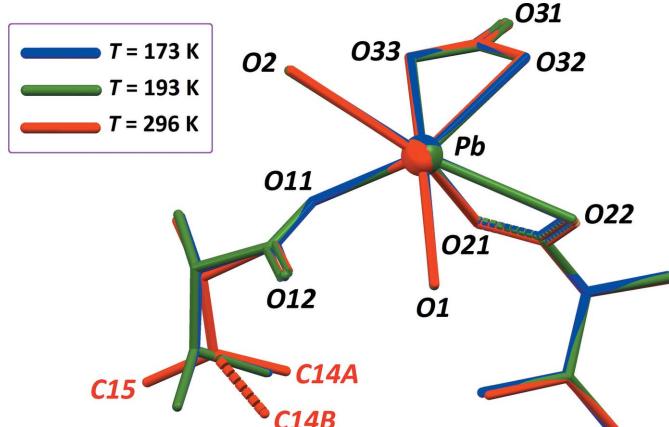

We have now determined the structure of the same compound at room temperature (Fig. 1). One L-valine ligand has a different conformation at room temperature, with one methyl group disordered over two positions, C14A and C14B, a feature not present at low

**Figure 1**

The asymmetric unit for the title complex, with displacement ellipsoids at the 30% probability level. The chosen asymmetric unit is identical to that used in Saunders *et al.* (2011), as well as the labeling scheme. H atoms bonded to C atoms are omitted for clarity. Atoms C14A and C14B are disordered sites for C14 and were refined isotropically.

temperature. The positions of the other ligands around Pb<sup>II</sup> are unchanged at 296 K (see Fig. 2 for a fit between the three refinements).

A comparison of the Pb···O distances in the coordination sphere of the metal at  $T = 173$ , 193 and 296 K is given in Table 1. No clear trend can be extracted from these data, because uncertainties for the 173 and 296 K refinements are four to six times higher than those of the 193 K refinement. However, these distances are informative regarding the mode of coordination of the L-valine ligands. The first one is clearly monodentate, since the Pb···O12 distance is greater than 3.2 Å at any temperature. The situation for the other ligand is more ambiguous. Distance Pb···O22 increases as  $T$  increases, to reach 2.934 (10) Å at 296 K. Taking into account the upper limit of 2.9 Å for a Pb—O bond, retained by Saunders *et al.* (see Fig. 5 in Saunders *et al.*, 2011), we could consider that the

**Figure 2**

A fit between the refinements of the title compound at  $T = 173$  (blue), 193 (green) and 296 K (red). The fit was carried out using Pb and O atoms of cation  $[\text{Pb}(\text{H}_2\text{O})_2(\text{L-valine})_2(\text{NO}_3)]^+$  (Macrae *et al.*, 2008). Labels are for the  $T = 296$  K refinement. Sites C14A and C14B correspond to a single atom disordered over two positions.

**Table 1**

Comparison for distances in the coordination sphere (Å) at different temperatures.

Bond <sup>a</sup>	$T = 173$ K <sup>b</sup>	$T = 193$ K <sup>c</sup>	$T = 296$ K <sup>d</sup>
Pb···O1	2.510 (12)	2.512 (3)	2.504 (14)
Pb···O2	2.891	2.915 (2)	2.891 (13)
Pb···O11	2.442 (10)	2.459 (2)	2.462 (12)

N21—H21A···O2 <sup>vi</sup>	0.93	2.24	2.947 (19)	132
N21—H21B···O42 <sup>v</sup>	0.93	2.03	2.924 (18)	160
N21—H21C···O41	0.93	1.86	2.785 (18)	177

Symmetry codes: (i)  $x - 1, y, z$ ; (ii)  $-x + 1, y - \frac{1}{2}, -z + \frac{1}{2}$ ; (iii)  $-x, y - \frac{1}{2}, -z + \frac{1}{2}$ ; (iv)  $x + 1, y - 1, z$ ; (v)  $x + 1, y, z$ ; (vi)  $-x + 1, y + \frac{1}{2}, -z + \frac{1}{2}$ .

carbonyl group C21=O22 is not engaged in coordination. As a consequence, both zwitterionic valine ligands in our refinement should be considered as monodentate (Fig. 1), in contrast with the low-temperature refinements, described with  $\kappa O$  and  $\kappa^2 O, O'$  coordination modes.

Using the same criterion, the complex at  $T = 296$  K is not a polymeric compound, since the shortest intermolecular Pb···O<sub>nitrate</sub> distance is Pb···O31<sup>i</sup> = 2.996 (16) Å [symmetry code: (i)  $-1 + x, y, z$ ]. This distance was 2.95 (1) Å at 173 K and 2.969 (3) Å at 193 K. As commented by Saunders *et al.*, these distances close to the 2.9 Å threshold mean that ‘the assignment of the environment of lead in these compounds as hemi- or holodirected is arbitrary’.

In the here reported structure, all H atoms bonded to heteroatoms are engaged in hydrogen bonds (Table 2) of variable strengths.

### Synthesis and crystallization

2 mmol (0.67 g) of Pb(NO<sub>3</sub>)<sub>2</sub> were dissolved in 20 ml of previously degassed distilled water. To this solution, 4 mmol (0.47 g) of solid valine were added in several portions and with constant stirring. The pH value was adjusted to 5.0 with NaOH 0.1 M, and the solution was left to rest. Two weeks later, suitable crystals were collected.

## Refinement

Crystal data, data collection and structure refinement details are summarized in Table 3. The structure refinement was started using coordinates deposited for ESAPET01, since the first structure, ESAPET, was collected with permuted cell axis

for the orthorhombic cell. Atom C14 is disordered over two sites, C14A and C14B, for which occupancies converged to 0.56 (3) and 0.44 (3). Both atoms C14A and C14B were refined isotropically with a common displacement parameter, which was fixed in the last cycles, in order to avoid correlation with the refined occupancy. Bond lengths C13–C15 and C13–C14(A,B) in this *iso*-propyl group were restrained to 1.54 (2) Å. It was also necessary to refine nitrate atom N30 isotropically, otherwise a non-positive definite ellipsoid is obtained for this atom. C- and N- bonded H atoms were placed in calculated positions, with fixed bond lengths C–H = 0.96 Å (methyl), 0.98 Å (methine) and N–H = 0.93 Å (ammonium, with free rotation about the C–N bonds). Water H atoms were found in a difference map and refined with restrained distances: 0.85 (2) Å for O–H bonds and 1.40 (3) Å for H· · · H separation in each water molecule. Displacement parameters for H atoms were calculated as  $U_{\text{iso}}(\text{H}) = xU_{\text{eq}}(\text{carrier atom})$ , with  $x = 1.5$  (methyl, ammonium, water) or  $x = 1.2$  (methine).
